

**n PIN DESCRIPTIONS**

Name	Function
<b>A0-A17 Address Input</b>	These 18 address inputs select one of the 262,144 x 16-bit in the RAM
<b><math>\overline{\text{CE}}</math> Chip Enable Input</b>	$\overline{\text{CE}}$ is active LOW. Chip enable must be active when data read from or write to the device. If chip enable is not active, the device is deselected and is in standby power mode. The DQ pins will be in the high impedance state when the device is deselected.
<b><math>\overline{\text{WE}}</math> Write Enable Input</b>	The write enable input is active LOW and controls read and write operations. With the chip selected, when $\overline{\text{WE}}$ is HIGH and $\overline{\text{OE}}$ is LOW, output data will be present on the DQ pins; when $\overline{\text{WE}}$ is LOW, the data present on the DQ pins will be written into the selected memory location.
<b><math>\overline{\text{OE}}</math> Output Enable Input</b>	The output enable input is active LOW. If the output enable is active while the chip is selected and the write enable is inactive, data will be present on the DQ pins and they will be enabled. The DQ pins will be in the high impedance state when $\overline{\text{OE}}$ is inactive.
<b><math>\overline{\text{LB}}</math> and <math>\overline{\text{UB}}</math> Data Byte Control Input</b>	Lower byte and upper byte data input/output control pins.
<b>DQ0-DQ15 Data Input/Output Ports</b>	There 16 bi-directional ports are used to read data from or write data into the RAM.
<b>V<sub>CC</sub></b>	Power Supply
<b>V<sub>SS</sub></b>	Ground

**NOTES:**

1.  $\overline{WE}$  is high in read Cycle.
2. Device is continuously selected when  $\overline{CE} = V_{IL}$ .
3. Address valid prior to or coincident with  $\overline{CE}$  transition low.
4.  $\overline{OE} = V_{IL}$ .
5. Transition is measured  $\pm 500\text{mV}$  from steady state with  $C_L = 5\text{pF}$ .  
The parameter is guaranteed but not 100% tested.

**n SWITCHING WAVEFORMS (WRITE CYCLE)**
**WRITE CYCLE 1 <sup>(1)</sup>**

**WRITE CYCLE 2** <sup>(1,6)</sup>

**NOTES:**

1.  $\overline{WE}$  must be high during address transitions.
2. The internal write time of the memory is defined by the overlap of  $\overline{CE}$  and  $\overline{WE}$  low. All signals must be active to initiate a write and any one signal can terminate a write by going inactive. The data input setup and hold timing should be referenced to the second transition edge of the signal that terminates the write.
3.  $t_{WR}$  is measured from the earlier of  $\overline{CE}$  or  $\overline{WE}$  going high at the end of write cycle.
4. During this period, DQ pins are in the output state so that the input signals of opposite phase to the outputs must not be applied.
5. If the  $\overline{CE}$  low transition occurs simultaneously with the  $\overline{WE}$  low transitions or after the  $\overline{WE}$  transition, output remain in a high impedance state.
6.  $\overline{OE}$  is continuously low ( $\overline{OE} = V_{IL}$ ).
7.  $D_{OUT}$  is the same phase of write data of this write cycle.
8.  $D_{OUT}$  is the read data of next address.
9. If  $\overline{CE}$  is low during this period, DQ pins are in the output state. Then the data input signals of opposite phase to the outputs must not be applied to them.
10. Transition is measured  $\pm 500\text{mV}$  from steady state with  $C_L = 5\text{pF}$ .  
The parameter is guaranteed but not 100% tested.
11.  $t_{CW}$  is measured from the later of  $\overline{CE}$  going low to the end of write.
12. The change of Read/Write cycle must accompany with  $\overline{CE}$  or address toggled.
