Register 6:	PWM Interrupt Enable (PWMINTEN), offset 0x014	535
Register 7:	PWM Raw Interrupt Status (PWMRIS), offset 0x018	536
Register 8:	PWM Interrupt Status and Clear (PWMISC), offset 0x01C	537
Register 9:	PWM Status (PWMSTATUS), offset 0x020	538
Register 10:	PWM0 Control (PWM0CTL), offset 0x040	539
Register 11:	PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044	543
Register 12:	PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048	545
Register 13:	PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C	546
Register 14:	PWM0 Load (PWM0LOAD), offset 0x050	547
Register 15:	PWM0 Counter (PWM0COUNT), offset 0x054	548
Register 16:	PWM0 Compare A (PWM0CMPA), offset 0x058	549
Register 17:	PWM0 Compare B (PWM0CMPB), offset 0x05C	550
Register 18:	PWM0 Generator A Control (PWM0GENA), offset 0x060	551
Register 19:	PWM0 Generator B Control (PWM0GENB), offset 0x064	554
Register 20:	PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068	557
Register 21:	PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C	558
Register 22:	PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070	559

About This Document

This data sheet provides reference information for the LM3S2671 microcontroller, describing the functional blocks of the system-on-chip (SoC) device designed around the ARM® Cortex™-M3 core.

Audience

This manual is intended for system software developers, hardware designers, and application developers.

About This Manual

This document is organized into sections that correspond to each major feature.

Related Documents

This documentation list was current as of publication date. Please check the Luminary Micro web site for additional documentation, including application notes and white papers.

Documentation Conventions

This document uses the conventions shown in Table 1 on page 20.

Table 1. Documentation Conventions

Notation	Meaning
General Register Notation	
REGISTER	APB registers are indicated in uppercase bold. For example, PBORCTL is the Power-On and Brown-Out Reset Control register. If a register name contains a lowercase n, it represents more than one register. For example, SRCRn represents any (or all) of the three Software Reset Control registers: SRCR0 , SRCR1 , and SRCR2 .
bit	A single bit in a register.
bit field	Two or more consecutive and related bits.
offset 0xnnn	A hexadecimal increment to a register's address, relative to that module's base address as specified in "Memory Map" on page 45.

Notation	Meaning
Register <i>N</i>	Registers are numbered consecutively throughout the document to aid in referencing them. The register number has no meaning to software.
reserved	Register bits marked <i>reserved</i> are reserved for future use. In most cases, reserved bits are set to 0; however, user software should not rely on the value of a reserved bit. To provide software compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
yy:xx	The range of register bits inclusive from xx to yy. For example, 31:15 means bits 15 through 31 in that register.
Register Bit/Field Types	This value in the register bit diagram indicates whether software running on the controller can change the value of the bit field.
RC	Software can read this field. The bit or field is cleared by hardware after reading the bit/field.
RO	Software can read this field. Always write the chip reset value.
R/W	Software can read or write this field.
R/W1C	Software can read or write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. This register type is primarily used for clearing interrupt status bits where the read operation provides the interrupt status and the write of the read value clears only the interrupts being reported at the time the register was read.
R/W1S	Software can read or write a 1 to this field. A write of a 0 to a R/W1S bit does not affect the bit value in the register.
W1C	Software can write this field. A write of a 0 to a W1C bit does not affect the bit value in the register. A write of a 1 clears the value of the bit in the register; the remaining bits remain unchanged. A read of the register returns no meaningful data. This register is typically used to clear the corresponding bit in an interrupt register.
WO	Only a write by software is valid; a read of the register returns no meaningful data.
Register Bit/Field Reset Value	This value in the register bit diagram shows the bit/field value after any reset, unless noted.
0	Bit cleared to 0 on chip reset.
1	Bit set to 1 on chip reset.
-	Nondeterministic.
Pin/Signal Notation	
[]	Pin alternate function; a pin defaults to the signal without the brackets.
pin	Refers to the physical connection on the package.
signal	Refers to the electrical signal encoding of a pin.
assert a signal	Change the value of the signal from the logically False state to the logically True state. For active High signals, the asserted signal value is 1 (High); for active Low signals, the asserted signal value is 0 (Low). The active polarity (High or Low) is defined by the signal name (see <code>SIGNAL</code> and <code>SIGNAL</code> below).
deassert a signal	Change the value of the signal from the logically True state to the logically False state.
<code>SIGNAL</code>	Signal names are in uppercase and in the Courier font. An overbar on a signal name indicates that it is active Low. To assert <code>SIGNAL</code> is to drive it Low; to deassert <code>SIGNAL</code> is to drive it High.
<code>SIGNAL</code>	Signal names are in uppercase and in the Courier font. An active High signal has no overbar. To assert <code>SIGNAL</code> is to drive it High; to deassert <code>SIGNAL</code> is to drive it Low.
Numbers	
X	An uppercase X indicates any of several values is allowed, where X can be any legal pattern. For example, a binary value of 0X00 can be either 0100 or 0000, a hex value of 0xX is 0x0 or 0x1, and so on.

Notation	Meaning
0x	Hexadecimal numbers have a prefix of 0x. For example, 0x00FF is the hexadecimal number FF. All other numbers within register tables are assumed to be binary. Within conceptual information, binary numbers are indicated with a b suffix, for example, 1011b, and decimal numbers are written without a prefix or suffix.

1 Architectural Overview

The Luminary Micro Stellaris[®] family of microcontrollers—the first ARM[®] Cortex™-M3 based controllers—brings high-performance 32-bit computing to cost-sensitive embedded microcontroller applications. These pioneering parts deliver customers 32-bit performance at a cost equivalent to legacy 8- and 16-bit devices, all in a package with a small footprint.

The Stellaris[®] family offers efficient performance and extensive integration, favorably positioning the device into cost-conscious applications requiring significant control-processing and connectivity capabilities. The Stellaris[®] LM3S2000 series, designed for Controller Area Network (CAN) applications, extends the Stellaris family with Bosch CAN networking technology, the golden standard in short-haul industrial networks. The Stellaris[®] LM3S2000 series also marks the first integration of CAN capabilities with the revolutionary Cortex-M3 core.

The LM3S2671 microcontroller is targeted for industrial applications, including remote monitoring, electronic point-of-sale machines, test and measurement equipment, network appliances and switches, factory automation, HVAC and building control, gaming equipment, motion control, medical instrumentation, and fire and security.

In addition, the LM3S2671 microcontroller offers the advantages of ARM's widely available development tools, System-on-Chip (SoC) infrastructure IP applications, and a large user community. Additionally, the microcontroller uses ARM's Thumb[®]-compatible Thumb-2 instruction set to reduce memory requirements and, thereby, cost. Finally, the LM3S2671 microcontroller is code-compatible to all members of the extensive Stellaris[®] family; providing flexibility to fit our customers' precise needs.

Luminary Micro offers a complete solution to get to market quickly, with evaluation and development boards, white papers and application notes, an easy-to-use peripheral driver library, and a strong support, sales, and distributor network. See “Ordering and Contact Information” on page 622 for ordering information for Stellaris[®] family devices.

1.1 Product Features

The LM3S2671 microcontroller includes the following product features:

- 32-Bit RISC Performance
 - 32-bit ARM[®] Cortex™-M3 v7M architecture optimized for small-footprint embedded applications
 - System timer (SysTick), providing a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism
 - Thumb[®]-compatible Thumb-2-only instruction set processor core for high code density
 - 50-MHz operation
 - Hardware-division and single-cycle-multiplication
 - Integrated Nested Vectored Interrupt Controller (NVIC) providing deterministic interrupt handling
 - 29 interrupts with eight priority levels

- Memory protection unit (MPU), providing a privileged mode for protected operating system functionality
- Unaligned data access, enabling data to be efficiently packed into memory
- Atomic bit manipulation (bit-banding), delivering maximum memory utilization and streamlined peripheral control
- Internal Memory
 - 128 KB single-cycle flash
 - User-managed flash block protection on a 2-KB block basis
 - User-managed flash data programming
 - User-defined and managed flash-protection block
 - 32 KB single-cycle SRAM
 - Pre-programmed ROM containing the Stellaris[®] family peripheral driver library (DriverLib) and Stellaris[®] boot loader
- DMA Controller
 - ARM PrimeCell[®] 32-channel configurable μ DMA controller
 - Support for multiple transfer modes:
 - Basic, for simple transfer scenarios
 - Ping-pong, for continuous data flow to/from peripherals
 - Scatter-gather, from a programmable list of arbitrary transfers initiated from a single request
 - Dedicated channels for supported peripherals
 - One channel each for receive and transmit path for bidirectional peripherals
 - Dedicated channel for software-initiated transfers
 - Independently configured and operated channels
 - Per-channel configurable bus arbitration scheme
 - Two levels of priority
 - Design optimizations for improved bus access performance between μ DMA controller and the processor core:
 - μ DMA controller access is subordinate to core access
 - RAM striping
 - Peripheral bus segmentation
 - Data sizes of 8, 16, and 32 bits

- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable device requests
- Optional software initiated requests for any channel
- Interrupt on transfer completion, with a separate interrupt per channel
- General-Purpose Timers
 - Four General-Purpose Timer Modules (GPTM), each of which provides two 16-bit timers. Each GPTM can be configured to operate independently:
 - As a single 32-bit timer
 - As one 32-bit Real-Time Clock (RTC) to event capture
 - For Pulse Width Modulation (PWM)
 - To trigger analog-to-digital conversions
 - 32-bit Timer modes
 - Programmable one-shot timer
 - Programmable periodic timer
 - Real-Time Clock when using an external 32.768-KHz clock as the input
 - User-enabled stalling in periodic and one-shot mode when the controller asserts the CPU Halt flag during debug
 - ADC event trigger
 - 16-bit Timer modes
 - General-purpose timer function with an 8-bit prescaler
 - Programmable one-shot timer
 - Programmable periodic timer
 - User-enabled stalling when the controller asserts CPU Halt flag during debug
 - ADC event trigger
 - 16-bit Input Capture modes
 - Input edge count capture
 - Input edge time capture
 - 16-bit PWM mode
 - Simple PWM mode with software-programmable output inversion of the PWM signal
- ARM FiRM-compliant Watchdog Timer

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the controller asserts the CPU Halt flag during debug
- Controller Area Network (CAN)
 - Supports CAN protocol version 2.0 part A/B
 - Bit rates up to 1Mb/s
 - 32 message objects, each with its own identifier mask
 - Maskable interrupt
 - Disable automatic retransmission mode for TTCAN
 - Programmable loop-back mode for self-test operation
- Synchronous Serial Interface (SSI)
 - Master or slave operation
 - Programmable clock bit rate and prescale
 - Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
 - Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
 - Programmable data frame size from 4 to 16 bits
 - Internal loopback test mode for diagnostic/debug testing
 - Direct memory access (DMA)
- UART
 - Fully programmable 16C550-type UART with IrDA support
 - Separate 16x8 transmit (TX) and 16x12 receive (RX) FIFOs to reduce CPU interrupt service loading
 - Programmable baud-rate generator allowing speeds up to 3.125 Mbps
 - Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
 - FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8

- Standard asynchronous communication bits for start, stop, and parity
- False-start-bit detection
- Line-break generation and detection
- Direct memory access (DMA)
- ADC
 - Single- and differential-input configurations
 - Four 10-bit channels (inputs) when used as single-ended inputs
 - Sample rate of 500 thousand samples/second
 - Flexible, configurable analog-to-digital conversion
 - Four programmable sample conversion sequences from one to eight entries long, with corresponding conversion result FIFOs
 - Each sequence triggered by software or internal event (timers, analog comparators, PWM or GPIO)
 - On-chip temperature sensor
- Analog Comparators
 - Three independent integrated analog comparators
 - Configurable for output to: drive an output pin or generate an interrupt
 - Configurable for output to: drive an output pin, generate an interrupt, or initiate an ADC sample sequence
 - Compare external pin input to external pin input or to internal programmable voltage reference
- I²C
 - Master and slave receive and transmit operation with transmission speed up to 100 Kbps in Standard mode and 400 Kbps in Fast mode
 - Interrupt generation
 - Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- PWM
 - One PWM generator blocks, each with one 16-bit counter, two comparators, a PWM generator, and a dead-band generator
 - One fault inputs in hardware to condition low-latency shutdown
 - One 16-bit counter

- Runs in Down or Up/Down mode
- Output frequency controlled by a 16-bit load value
- Load value updates can be synchronized
- Produces output signals at zero and load value
- Two PWM comparators
 - Comparator value updates can be synchronized
 - Produces output signals on match
- PWM generator
 - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
 - Produces two independent PWM signals
- Dead-band generator
 - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
 - Can be bypassed, leaving input PWM signals unmodified
- Flexible output control block with PWM output enable of each PWM signal
 - PWM output enable of each PWM signal
 - Optional output inversion of each PWM signal (polarity control)
 - Optional fault handling for each PWM signal
 - Synchronization of timers in the PWM generator blocks
 - Synchronization of timer/comparator updates across the PWM generator blocks
 - Interrupt status summary of the PWM generator blocks
- Can initiate an ADC sample sequence
- GPIOs
 - 3-33 GPIOs, depending on configuration
 - 5-V-tolerant input/outputs
 - Programmable interrupt generation as either edge-triggered or level-sensitive
 - Low interrupt latency; as low as 6 cycles and never more than 12 cycles
 - Bit masking in both read and write operations through address lines
 - Can initiate an ADC sample sequence

- Pins configured as digital inputs are Schmitt-triggered.
- Programmable control for GPIO pad configuration:
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
 - Slew rate control for the 8-mA drive
 - Open drain enables
 - Digital input enables
- Power
 - On-chip Low Drop-Out (LDO) voltage regulator, with programmable output user-adjustable from 2.25 V to 2.75 V
 - Low-power options on controller: Sleep and Deep-sleep modes
 - Low-power options for peripherals: software controls shutdown of individual peripherals
 - User-enabled LDO unregulated voltage detection and automatic reset
 - 3.3-V supply brown-out detection and reporting via interrupt or reset
- Flexible Reset Sources
 - Power-on reset (POR)
 - Reset pin assertion
 - Brown-out (BOR) detector alerts to system power drops
 - Software reset
 - Watchdog timer reset
 - Internal low drop-out (LDO) regulator output goes unregulated
- Additional Features
 - Six reset sources
 - Programmable clock source control
 - Clock gating to individual peripherals for power savings
 - IEEE 1149.1-1990 compliant Test Access Port (TAP) controller
 - Debug access via JTAG and Serial Wire interfaces
 - Full JTAG boundary scan
- Industrial-range 64-pin RoHS-compliant LQFP package

1.2 Target Applications

- Remote monitoring
- Electronic point-of-sale (POS) machines
- Test and measurement equipment
- Network appliances and switches
- Factory automation
- HVAC and building control
- Gaming equipment
- Motion control
- Medical instrumentation
- Fire and security
- Power and energy
- Transportation

1.3 High-Level Block Diagram

Figure 1-1 on page 31 represents the full set of features in the Stellaris[®] 2000 series of devices; not all features may be available on the LM3S2671 microcontroller.

Figure 1-1. Stellaris[®] 2000 Series High-Level Block Diagram

1.4 Functional Overview

The following sections provide an overview of the features of the LM3S2671 microcontroller. The page number in parenthesis indicates where that feature is discussed in detail. Ordering and support information can be found in “Ordering and Contact Information” on page 622.

1.4.1 ARM Cortex™-M3

1.4.1.1 Processor Core (see page 39)

All members of the Stellaris® product family, including the LM3S2671 microcontroller, are designed around an ARM Cortex™-M3 processor core. The ARM Cortex-M3 processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low-power consumption, while delivering outstanding computational performance and exceptional system response to interrupts.

“ARM Cortex-M3 Processor Core” on page 39 provides an overview of the ARM core; the core is detailed in the *ARM® Cortex™-M3 Technical Reference Manual*.

1.4.1.2 System Timer (SysTick)

Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer which fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter. Software can use this to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field in the control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

1.4.1.3 Nested Vectored Interrupt Controller (NVIC)

The LM3S2671 controller includes the ARM Nested Vectored Interrupt Controller (NVIC) on the ARM® Cortex™-M3 core. The NVIC and Cortex-M3 prioritize and handle all exceptions. All exceptions are handled in Handler Mode. The processor state is automatically stored to the stack on an exception, and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, which enables efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration. Software can set eight priority levels on 7 exceptions (system handlers) and 29 interrupts.

“Interrupts” on page 48 provides an overview of the NVIC controller and the interrupt map. Exceptions and interrupts are detailed in the *ARM® Cortex™-M3 Technical Reference Manual*.

1.4.1.4 Direct Memory Access (see page 156)

The LM3S2671 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μDMA). The μDMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the expanded available bus bandwidth. The μDMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported peripheral and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μDMA controller also supports sophisticated transfer modes such as ping-pong and scatter-gather, which allows the processor to set up a list of transfer tasks for the controller.

1.4.2 Motor Control Peripherals

To enhance motor control, the LM3S2671 controller features Pulse Width Modulation (PWM) outputs.

1.4.2.1 PWM

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

On the LM3S2671, PWM motion control functionality can be achieved through:

- Dedicated, flexible motion control hardware using the PWM pins
- The motion control features of the general-purpose timers using the CCP pins

PWM Pins (see page 522)

The LM3S2671 PWM module consists of one PWM generator blocks and a control block. Each PWM generator block contains one timer (16-bit down or up/down counter), two comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that can either be independent signals or a single pair of complementary signals with dead-band delays inserted. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins.

CCP Pins (see page 268)

The General-Purpose Timer Module's CCP (Capture Compare PWM) pins are software programmable to support a simple PWM mode with a software-programmable output inversion of the PWM signal.

Fault Pins (see “Fault Conditions”)

The LM3S2671 PWM module includes one fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled.

1.4.3 Analog Peripherals

To handle analog signals, the LM3S2671 microcontroller offers an Analog-to-Digital Converter (ADC).

For support of analog signals, the LM3S2671 microcontroller offers three analog comparators.

1.4.3.1 ADC (see page 319)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number.

The LM3S2671 ADC module features 10-bit conversion resolution and supports four input channels, plus an internal temperature sensor. Four buffered sample sequences allow rapid sampling of up to eight analog input sources without controller intervention. Each sample sequence provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequence priority.

1.4.3.2 Analog Comparators (see page 509)

An analog comparator is a peripheral that compares two analog voltages, and provides a logical output that signals the comparison result.

The LM3S2671 microcontroller provides three independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

A comparator can compare a test voltage against any one of these voltages:

- An individual external reference voltage
- A shared single external reference voltage
- A shared internal reference voltage

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

1.4.4 Serial Communications Peripherals

The LM3S2671 controller supports both asynchronous and synchronous serial communications with:

- One fully programmable 16C550-type UART
- One SSI module
- One I²C module
- One CAN unit

1.4.4.1 UART (see page 351)

A Universal Asynchronous Receiver/Transmitter (UART) is an integrated circuit used for RS-232C serial communications, containing a transmitter (parallel-to-serial converter) and a receiver (serial-to-parallel converter), each clocked separately.

The LM3S2671 controller includes one fully programmable 16C550-type UART that supports data transfer speeds up to 3.125 Mbps. (Although similar in functionality to a 16C550 UART, it is not register-compatible.) In addition, each UART is capable of supporting IrDA.

Separate 16x8 transmit (TX) and 16x12 receive (RX) FIFOs reduce CPU interrupt service loading. The UART can generate individually masked interrupts from the RX, TX, modem status, and error conditions. The module provides a single combined interrupt when any of the interrupts are asserted and are unmasked.

1.4.4.2 SSI (see page 394)

Synchronous Serial Interface (SSI) is a four-wire bi-directional communications interface.

The LM3S2671 controller includes one SSI module that provides the functionality for synchronous serial communications with peripheral devices, and can be configured to use the Freescale SPI, MICROWIRE, or TI synchronous serial interface frame formats. The size of the data frame is also configurable, and can be set between 4 and 16 bits, inclusive.

The SSI module performs serial-to-parallel conversion on data received from a peripheral device, and parallel-to-serial conversion on data transmitted to a peripheral device. The TX and RX paths are buffered with internal FIFOs, allowing up to eight 16-bit values to be stored independently.

The SSI module can be configured as either a master or slave device. As a slave device, the SSI module can also be configured to disable its output, which allows a master device to be coupled with multiple slave devices.

The SSI module also includes a programmable bit rate clock divider and prescaler to generate the output serial clock derived from the SSI module's input clock. Bit rates are generated based on the input clock and the maximum bit rate is determined by the connected peripheral.

1.4.4.3 I²C (see page 433)

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL).

The I²C bus interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacture.

The LM3S2671 controller includes one I²C module that provides the ability to communicate to other IC devices over an I²C bus. The I²C bus supports devices that can both transmit and receive (write and read) data.

Devices on the I²C bus can be designated as either a master or a slave. The I²C module supports both sending and receiving data as either a master or a slave, and also supports the simultaneous operation as both a master and a slave. The four I²C modes are: Master Transmit, Master Receive, Slave Transmit, and Slave Receive.

A Stellaris[®] I²C module can operate at two speeds: Standard (100 Kbps) and Fast (400 Kbps).

Both the I²C master and slave can generate interrupts. The I²C master generates interrupts when a transmit or receive operation completes (or aborts due to an error). The I²C slave generates interrupts when data has been sent or requested by a master.

1.4.4.4 Controller Area Network (see page 468)

Controller Area Network (CAN) is a multicast shared serial-bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, now it is used in many embedded control applications (for example, industrial or medical). Bit rates up to 1Mb/s are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kb/s at 500m).

A transmitter sends a message to all CAN nodes (broadcasting). Each node decides on the basis of the identifier received whether it should process the message. The identifier also determines the priority that the message enjoys in competition for bus access. Each CAN message can transmit from 0 to 8 bytes of user information. The LM3S2671 includes one CAN units.

1.4.5 System Peripherals

1.4.5.1 Programmable GPIOs (see page 217)

General-purpose input/output (GPIO) pins offer flexibility for a variety of connections.

The Stellaris[®] GPIO module is comprised of five physical GPIO blocks, each corresponding to an individual GPIO port. The GPIO module is FIRM-compliant (compliant to the ARM Foundation IP for Real-Time Microcontrollers specification) and supports 3-33 programmable input/output pins. The number of GPIOs available depends on the peripherals being used (see “Signal Tables” on page 561 for the signals available to each GPIO pin).

The GPIO module features programmable interrupt generation as either edge-triggered or level-sensitive on all pins, programmable control for GPIO pad configuration, and bit masking in both read and write operations through address lines. Pins configured as digital inputs are Schmitt-triggered.

1.4.5.2 Four Programmable Timers (see page 262)

Programmable timers can be used to count or time external events that drive the Timer input pins.

The Stellaris[®] General-Purpose Timer Module (GPTM) contains four GPTM blocks. Each GPTM block provides two 16-bit timers/counters that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions.

When configured in 32-bit mode, a timer can run as a Real-Time Clock (RTC), one-shot timer or periodic timer. When in 16-bit mode, a timer can run as a one-shot timer or periodic timer, and can extend its precision by using an 8-bit prescaler. A 16-bit timer can also be configured for event capture or Pulse Width Modulation (PWM) generation.

1.4.5.3 Watchdog Timer (see page 296)

A watchdog timer can generate nonmaskable interrupts (NMIs) or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or to the failure of an external device to respond in the expected way.

The Stellaris[®] Watchdog Timer module consists of a 32-bit down counter, a programmable load register, interrupt generation logic, and a locking register.

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

1.4.6 Memory Peripherals

The LM3S2671 controller offers both single-cycle SRAM and single-cycle Flash memory.

1.4.6.1 SRAM (see page 127)

The LM3S2671 static random access memory (SRAM) controller supports 32 KB SRAM. The internal SRAM of the Stellaris[®] devices is located at offset 0x0000.0000 of the device memory map. To reduce the number of time-consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the new Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

1.4.6.2 Flash (see page 128)

The LM3S2671 Flash controller supports 128 KB of flash memory. The flash is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. These blocks are paired into a set of 2-KB blocks that can be individually protected. The blocks can be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those

blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

1.4.6.3 ROM

The LM3S2671 microcontroller ships with the Stellaris[®] family Peripheral Driver Library conveniently preprogrammed in read-only memory (ROM). The Stellaris[®] Peripheral Driver Library is a royalty-free software library for controlling on-chip peripherals, and includes a boot-loader capability. The library performs both peripheral initialization and peripheral control functions, with a choice of polled or interrupt-driven peripheral support, and takes full advantage of the stellar interrupt performance of the ARM[®] Cortex[™]-M3 core. No special pragmas or custom assembly code prologue/epilogue functions are required. For applications that require in-field programmability, the royalty-free Stellaris[®] boot loader included in the Stellaris[®] Peripheral Driver Library can act as an application loader and support in-field firmware updates.

1.4.7 Additional Features

1.4.7.1 Memory Map (see page 45)

A memory map lists the location of instructions and data in memory. The memory map for the LM3S2671 controller can be found in “Memory Map” on page 45. Register addresses are given as a hexadecimal increment, relative to the module’s base address as shown in the memory map.

The *ARM[®] Cortex[™]-M3 Technical Reference Manual* provides further information on the memory map.

1.4.7.2 JTAG TAP Controller (see page 51)

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is composed of the standard four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Luminary Micro JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core. This is implemented by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Luminary Micro JTAG instructions select the Luminary Micro TDO outputs. The multiplexer is controlled by the Luminary Micro JTAG controller, which has comprehensive programming for the ARM, Luminary Micro, and unimplemented JTAG instructions.

1.4.7.3 System Control and Clocks (see page 63)

System control determines the overall operation of the device. It provides information about the device, controls the clocking of the device and individual peripherals, and handles reset detection and reporting.

1.4.8 Hardware Details

Details on the pins and package can be found in the following sections:

- “Pin Diagram” on page 560
- “Signal Tables” on page 561
- “Operating Characteristics” on page 570
- “Electrical Characteristics” on page 571
- “Package Information” on page 582

2 ARM Cortex-M3 Processor Core

The ARM Cortex-M3 processor provides the core for a high-performance, low-cost platform that meets the needs of minimal memory implementation, reduced pin count, and low power consumption, while delivering outstanding computational performance and exceptional system response to interrupts. Features include:

- Compact core.
- Thumb-2 instruction set, delivering the high-performance expected of an ARM core in the memory size usually associated with 8- and 16-bit devices; typically in the range of a few kilobytes of memory for microcontroller class applications.
- Rapid application execution through Harvard architecture characterized by separate buses for instruction and data.
- Exceptional interrupt handling, by implementing the register manipulations required for handling an interrupt in hardware.
- Deterministic, fast interrupt processing: always 12 cycles, or just 6 cycles with tail-chaining
- External non-maskable interrupt signal (NMI) available for immediate execution of NMI handler for safety critical applications.
- Memory protection unit (MPU) to provide a privileged mode of operation for complex applications.
- Migration from the ARM7™ processor family for better performance and power efficiency.
- Full-featured debug solution with a:
 - Serial Wire JTAG Debug Port (SWJ-DP)
 - Flash Patch and Breakpoint (FPB) unit for implementing breakpoints
 - Data Watchpoint and Trigger (DWT) unit for implementing watchpoints, trigger resources, and system profiling
 - Instrumentation Trace Macrocell (ITM) for support of printf style debugging
 - Trace Port Interface Unit (TPIU) for bridging to a Trace Port Analyzer
- Optimized for single-cycle flash usage
- Three sleep modes with clock gating for low power
- Single-cycle multiply instruction and hardware divide
- Atomic operations
- ARM Thumb2 mixed 16-/32-bit instruction set
- 1.25 DMIPS/MHz

The Stellaris[®] family of microcontrollers builds on this core to bring high-performance 32-bit computing to cost-sensitive embedded microcontroller applications, such as factory automation and control, industrial control power devices, building and home automation, and stepper motors.

For more information on the ARM Cortex-M3 processor core, see the *ARM[®] Cortex[™]-M3 Technical Reference Manual*. For information on SWJ-DP, see the *ARM[®] CoreSight Technical Reference Manual*.

2.1 Block Diagram

Figure 2-1. CPU Block Diagram

2.2 Functional Description

Important: The *ARM[®] Cortex[™]-M3 Technical Reference Manual* describes all the features of an ARM Cortex-M3 in detail. However, these features differ based on the implementation. This section describes the Stellaris[®] implementation.

Luminary Micro has implemented the ARM Cortex-M3 core as shown in Figure 2-1 on page 40. As noted in the *ARM[®] Cortex[™]-M3 Technical Reference Manual*, several Cortex-M3 components are flexible in their implementation: SW/JTAG-DP, ETM, TPIU, the ROM table, the MPU, and the Nested Vectored Interrupt Controller (NVIC). Each of these is addressed in the sections that follow.

2.2.1 Serial Wire and JTAG Debug

Luminary Micro has replaced the ARM SW-DP and JTAG-DP with the ARM CoreSight™-compliant Serial Wire JTAG Debug Port (SWJ-DP) interface. This means Chapter 12, “Debug Port,” of the *ARM® Cortex™-M3 Technical Reference Manual* does not apply to Stellaris® devices.

The SWJ-DP interface combines the SWD and JTAG debug ports into one module. See the *CoreSight™ Design Kit Technical Reference Manual* for details on SWJ-DP.

2.2.2 Embedded Trace Macrocell (ETM)

ETM was not implemented in the Stellaris® devices. This means Chapters 15 and 16 of the *ARM® Cortex™-M3 Technical Reference Manual* can be ignored.

2.2.3 Trace Port Interface Unit (TPIU)

The TPIU acts as a bridge between the Cortex-M3 trace data from the ITM, and an off-chip Trace Port Analyzer. The Stellaris® devices have implemented TPIU as shown in Figure 2-2 on page 41. This is similar to the non-ETM version described in the *ARM® Cortex™-M3 Technical Reference Manual*, however, SWJ-DP only provides SWV output for the TPIU.

Figure 2-2. TPIU Block Diagram

2.2.4 ROM Table

The default ROM table was implemented as described in the *ARM® Cortex™-M3 Technical Reference Manual*.

2.2.5 Memory Protection Unit (MPU)

The Memory Protection Unit (MPU) is included on the LM3S2671 controller and supports the standard ARMv7 Protected Memory System Architecture (PMSA) model. The MPU provides full support for protection regions, overlapping protection regions, access permissions, and exporting memory attributes to the system.

2.2.6 Nested Vectored Interrupt Controller (NVIC)

The Nested Vectored Interrupt Controller (NVIC):

- Facilitates low-latency exception and interrupt handling
- Controls power management
- Implements system control registers

The NVIC supports up to 240 dynamically reprioritizable interrupts each with up to 256 levels of priority. The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts. The NVIC maintains knowledge of the stacked (nested) interrupts to enable tail-chaining of interrupts.

You can only fully access the NVIC from privileged mode, but you can pend interrupts in user-mode if you enable the Configuration Control Register (see the ARM® Cortex™-M3 Technical Reference Manual). Any other user-mode access causes a bus fault.

All NVIC registers are accessible using byte, halfword, and word unless otherwise stated.

2.2.6.1 Interrupts

The *ARM® Cortex™-M3 Technical Reference Manual* describes the maximum number of interrupts and interrupt priorities. The LM3S2671 microcontroller supports 29 interrupts with eight priority levels.

In addition to the peripheral interrupts, the system also provides for a non-maskable interrupt. The NMI is generally used in safety critical applications where the immediate execution of an interrupt handler is required. The NMI signal is available as an external signal so that it may be generated by external circuitry. The NMI is also used internally as part of the main oscillator verification circuitry. More information on the non-maskable interrupt is located in “Non-Maskable Interrupt” on page 66.

2.2.6.2 System Timer (SysTick)

Cortex-M3 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used in several different ways, for example:

- An RTOS tick timer which fires at a programmable rate (for example, 100 Hz) and invokes a SysTick routine.
- A high-speed alarm timer using the system clock.
- A variable rate alarm or signal timer—the duration is range-dependent on the reference clock used and the dynamic range of the counter.
- A simple counter. Software can use this to measure time to completion and time used.
- An internal clock source control based on missing/meeting durations. The COUNTFLAG bit-field in the control and status register can be used to determine if an action completed within a set duration, as part of a dynamic clock management control loop.

Functional Description

The timer consists of three registers:

- A control and status counter to configure its clock, enable the counter, enable the SysTick interrupt, and determine counter status.
- The reload value for the counter, used to provide the counter's wrap value.
- The current value of the counter.

A fourth register, the SysTick Calibration Value Register, is not implemented in the Stellaris® devices.

When enabled, the timer counts down from the reload value to zero, reloads (wraps) to the value in the SysTick Reload Value register on the next clock edge, then decrements on subsequent clocks. Writing a value of zero to the Reload Value register disables the counter on the next wrap. When the counter reaches zero, the COUNTFLAG status bit is set. The COUNTFLAG bit clears on reads.

Writing to the Current Value register clears the register and the COUNTFLAG status bit. The write does not trigger the SysTick exception logic. On a read, the current value is the value of the register at the time the register is accessed.

If the core is in debug state (halted), the counter will not decrement. The timer is clocked with respect to a reference clock. The reference clock can be the core clock or an external clock source.

SysTick Control and Status Register

Use the SysTick Control and Status Register to enable the SysTick features. The reset is 0x0000.0000.

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	COUNTFLAG	R/W	0	Count Flag Returns 1 if timer counted to 0 since last time this was read. Clears on read by application. If read by the debugger using the DAP, this bit is cleared on read-only if the MasterType bit in the AHB-AP Control Register is set to 0. Otherwise, the COUNTFLAG bit is not changed by the debugger read.
15:3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	CLKSOURCE	R/W	0	Clock Source Value Description 0 External reference clock. (Not implemented for Stellaris microcontrollers.) 1 Core clock If no reference clock is provided, it is held at 1 and so gives the same time as the core clock. The core clock must be at least 2.5 times faster than the reference clock. If it is not, the count values are unpredictable.
1	TICKINT	R/W	0	Tick Interrupt Value Description 0 Counting down to 0 does not generate the interrupt request to the NVIC. Software can use the COUNTFLAG to determine if ever counted to 0. 1 Counting down to 0 pends the SysTick handler.

Bit/Field	Name	Type	Reset	Description
0	ENABLE	R/W	0	Enable Value Description 0 Counter disabled. 1 Counter operates in a multi-shot way. That is, counter loads with the Reload value and then begins counting down. On reaching 0, it sets the COUNTFLAG to 1 and optionally pends the SysTick handler, based on TICKINT. It then loads the Reload value again, and begins counting.

SysTick Reload Value Register

Use the SysTick Reload Value Register to specify the start value to load into the current value register when the counter reaches 0. It can be any value between 1 and 0x00FF.FFFF. A start value of 0 is possible, but has no effect because the SysTick interrupt and COUNTFLAG are activated when counting from 1 to 0.

Therefore, as a multi-shot timer, repeated over and over, it fires every N+1 clock pulse, where N is any value from 1 to 0x00FF.FFFF. So, if the tick interrupt is required every 100 clock pulses, 99 must be written into the RELOAD. If a new value is written on each tick interrupt, so treated as single shot, then the actual count down must be written. For example, if a tick is next required after 400 clock pulses, 400 must be written into the RELOAD.

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	RELOAD	W1C	-	Reload Value to load into the SysTick Current Value Register when the counter reaches 0.

SysTick Current Value Register

Use the SysTick Current Value Register to find the current value in the register.

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	CURRENT	W1C	-	Current Value Current value at the time the register is accessed. No read-modify-write protection is provided, so change with care. This register is write-clear. Writing to it with any value clears the register to 0. Clearing this register also clears the COUNTFLAG bit of the SysTick Control and Status Register.

SysTick Calibration Value Register

The SysTick Calibration Value register is not implemented.

3 Memory Map

The memory map for the LM3S2671 controller is provided in Table 3-1 on page 45.

In this manual, register addresses are given as a hexadecimal increment, relative to the module's base address as shown in the memory map. See also Chapter 4, "Memory Map" in the *ARM® Cortex™-M3 Technical Reference Manual*.

a. All reserved space returns a bus fault when read or written.

- b. The unavailable flash will bus fault throughout this range.
- c. The unavailable SRAM will bus fault throughout this range.

4 Interrupts

The ARM Cortex-M3 processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. All exceptions are handled in Handler Mode. The processor state is automatically stored to the stack on an exception, and automatically restored from the stack at the end of the Interrupt Service Routine (ISR). The vector is fetched in parallel to the state saving, which enables efficient interrupt entry. The processor supports tail-chaining, which enables back-to-back interrupts to be performed without the overhead of state saving and restoration.

Table 4-1 on page 48 lists all exception types. Software can set eight priority levels on seven of these exceptions (system handlers) as well as on 29 interrupts (listed in Table 4-2 on page 49).

Priorities on the system handlers are set with the NVIC System Handler Priority registers. Interrupts are enabled through the NVIC Interrupt Set Enable register and prioritized with the NVIC Interrupt Priority registers. You also can group priorities by splitting priority levels into pre-emption priorities and subpriorities. All of the interrupt registers are described in Chapter 8, “Nested Vectored Interrupt Controller” in the *ARM® Cortex™-M3 Technical Reference Manual*.

Internally, the highest user-settable priority (0) is treated as fourth priority, after a Reset, NMI, and a Hard Fault. Note that 0 is the default priority for all the settable priorities.

If you assign the same priority level to two or more interrupts, their hardware priority (the lower position number) determines the order in which the processor activates them. For example, if both GPIO Port A and GPIO Port B are priority level 1, then GPIO Port A has higher priority.

See Chapter 5, “Exceptions” and Chapter 8, “Nested Vectored Interrupt Controller” in the *ARM® Cortex™-M3 Technical Reference Manual* for more information on exceptions and interrupts.

Table 4-1. Exception Types

Exception Type	Vector Number	Priority ^a	Description
-	0	-	Stack top is loaded from first entry of vector table on reset.
Reset	1	-3 (highest)	Invoked on power up and warm reset. On first instruction, drops to lowest priority (and then is called the base level of activation). This is asynchronous.
Non-Maskable Interrupt (NMI)	2	-2	Cannot be stopped or preempted by any exception but reset. This is asynchronous.
Hard Fault	3	-1	All classes of Fault, when the fault cannot activate due to priority or the configurable fault handler has been disabled. This is synchronous.
Memory Management	4	settable	MPU mismatch, including access violation and no match. This is synchronous. The priority of this exception can be changed.
Bus Fault	5	settable	Pre-fetch fault, memory access fault, and other address/memory related faults. This is synchronous when precise and asynchronous when imprecise. You can enable or disable this fault.
Usage Fault	6	settable	Usage fault, such as undefined instruction executed or illegal state transition attempt. This is synchronous.
-	7-10	-	Reserved.
SVCcall	11	settable	System service call with SVC instruction. This is synchronous.
Debug Monitor	12	settable	Debug monitor (when not halting). This is synchronous, but only active when enabled. It does not activate if lower priority than the current activation.

Exception Type	Vector Number	Priority ^a	Description
-	13	-	Reserved.
PendSV	14	settable	Pendable request for system service. This is asynchronous and only pended by software.
SysTick	15	settable	System tick timer has fired. This is asynchronous.
Interrupts	16 and above	settable	Asserted from outside the ARM Cortex-M3 core and fed through the NVIC (prioritized). These are all asynchronous. Table 4-2 on page 49 lists the interrupts on the LM3S2671 controller.

a. 0 is the default priority for all the settable priorities.

Table 4-2. Interrupts

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Description
0-15	-	Processor exceptions
16	0	GPIO Port A
17	1	GPIO Port B
18	2	GPIO Port C
19	3	GPIO Port D
20	4	GPIO Port E
21	5	UART0
22	6	Reserved
23	7	SSI0
24	8	I2C0
25	9	PWM Fault
26	10	PWM Generator 0
27-29	11-13	Reserved
30	14	ADC Sequence 0
31	15	ADC Sequence 1
32	16	ADC Sequence 2
33	17	ADC Sequence 3
34	18	Watchdog timer
35	19	Timer0 A
36	20	Timer0 B
37	21	Timer1 A
38	22	Timer1 B
39	23	Timer2 A
40	24	Timer2 B
41	25	Analog Comparator 0
42	26	Analog Comparator 1
43	27	Analog Comparator 2
44	28	System Control
45	29	Flash Control
46-50	30-34	Reserved
51	35	Timer3 A
52	36	Timer3 B

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Description
53-54	37-38	Reserved
55	39	CAN0
56-61	40-45	Reserved
62	46	uDMA Software
63	47	uDMA Error

5 JTAG Interface

The Joint Test Action Group (JTAG) port is an IEEE standard that defines a Test Access Port and Boundary Scan Architecture for digital integrated circuits and provides a standardized serial interface for controlling the associated test logic. The TAP, Instruction Register (IR), and Data Registers (DR) can be used to test the interconnections of assembled printed circuit boards and obtain manufacturing information on the components. The JTAG Port also provides a means of accessing and controlling design-for-test features such as I/O pin observation and control, scan testing, and debugging.

The JTAG port is comprised of four pins: TCK, TMS, TDI, and TDO. Data is transmitted serially into the controller on TDI and out of the controller on TDO. The interpretation of this data is dependent on the current state of the TAP controller. For detailed information on the operation of the JTAG port and TAP controller, please refer to the *IEEE Standard 1149.1-Test Access Port and Boundary-Scan Architecture*.

The Luminary Micro JTAG controller works with the ARM JTAG controller built into the Cortex-M3 core. This is implemented by multiplexing the TDO outputs from both JTAG controllers. ARM JTAG instructions select the ARM TDO output while Luminary Micro JTAG instructions select the Luminary Micro TDO outputs. The multiplexer is controlled by the Luminary Micro JTAG controller, which has comprehensive programming for the ARM, Luminary Micro, and unimplemented JTAG instructions.

The JTAG module has the following features:

- IEEE 1149.1-1990 compatible Test Access Port (TAP) controller
- Four-bit Instruction Register (IR) chain for storing JTAG instructions
- IEEE standard instructions:
 - BYPASS instruction
 - IDCODE instruction
 - SAMPLE/PRELOAD instruction
 - EXTEST instruction
 - INTEST instruction
- ARM additional instructions:
 - APACC instruction
 - DPACC instruction
 - ABORT instruction
- Integrated ARM Serial Wire Debug (SWD)

See the *ARM® Cortex™-M3 Technical Reference Manual* for more information on the ARM JTAG controller.

5.1 Block Diagram

Figure 5-1. JTAG Module Block Diagram

5.2 Functional Description

A high-level conceptual drawing of the JTAG module is shown in Figure 5-1 on page 52. The JTAG module is composed of the Test Access Port (TAP) controller and serial shift chains with parallel update registers. The TAP controller is a simple state machine controlled by the TCK and TMS inputs. The current state of the TAP controller depends on the sequence of values captured on TMS at the rising edge of TCK. The TAP controller determines when the serial shift chains capture new data, shift data from TDI towards TDO, and update the parallel load registers. The current state of the TAP controller also determines whether the Instruction Register (IR) chain or one of the Data Register (DR) chains is being accessed.

The serial shift chains with parallel load registers are comprised of a single Instruction Register (IR) chain and multiple Data Register (DR) chains. The current instruction loaded in the parallel load register determines which DR chain is captured, shifted, or updated during the sequencing of the TAP controller.

Some instructions, like EXTEST and INTEST, operate on data currently in a DR chain and do not capture, shift, or update any of the chains. Instructions that are not implemented decode to the BYPASS instruction to ensure that the serial path between TDI and TDO is always connected (see Table 5-2 on page 58 for a list of implemented instructions).

See “JTAG and Boundary Scan” on page 578 for JTAG timing diagrams.

5.2.1 JTAG Interface Pins

The JTAG interface consists of four standard pins: TCK, TMS, TDI, and TDO. These pins and their associated reset state are given in Table 5-1 on page 53. Detailed information on each pin follows.

Table 5-1. JTAG Port Pins Reset State

Pin Name	Data Direction	Internal Pull-Up	Internal Pull-Down	Drive Strength	Drive Value
TCK	Input	Enabled	Disabled	N/A	N/A
TMS	Input	Enabled	Disabled	N/A	N/A
TDI	Input	Enabled	Disabled	N/A	N/A
TDO	Output	Enabled	Disabled	2-mA driver	High-Z

5.2.1.1 Test Clock Input (TCK)

The TCK pin is the clock for the JTAG module. This clock is provided so the test logic can operate independently of any other system clocks. In addition, it ensures that multiple JTAG TAP controllers that are daisy-chained together can synchronously communicate serial test data between components. During normal operation, TCK is driven by a free-running clock with a nominal 50% duty cycle. When necessary, TCK can be stopped at 0 or 1 for extended periods of time. While TCK is stopped at 0 or 1, the state of the TAP controller does not change and data in the JTAG Instruction and Data Registers is not lost.

By default, the internal pull-up resistor on the TCK pin is enabled after reset. This assures that no clocking occurs if the pin is not driven from an external source. The internal pull-up and pull-down resistors can be turned off to save internal power as long as the TCK pin is constantly being driven by an external source.

5.2.1.2 Test Mode Select (TMS)

The TMS pin selects the next state of the JTAG TAP controller. TMS is sampled on the rising edge of TCK. Depending on the current TAP state and the sampled value of TMS, the next state is entered. Because the TMS pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TMS to change on the falling edge of TCK.

Holding TMS high for five consecutive TCK cycles drives the TAP controller state machine to the Test-Logic-Reset state. When the TAP controller enters the Test-Logic-Reset state, the JTAG module and associated registers are reset to their default values. This procedure should be performed to initialize the JTAG controller. The JTAG Test Access Port state machine can be seen in its entirety in Figure 5-2 on page 55.

By default, the internal pull-up resistor on the TMS pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC1/TMS; otherwise JTAG communication could be lost.

5.2.1.3 Test Data Input (TDI)

The TDI pin provides a stream of serial information to the IR chain and the DR chains. TDI is sampled on the rising edge of TCK and, depending on the current TAP state and the current instruction, presents this data to the proper shift register chain. Because the TDI pin is sampled on the rising edge of TCK, the *IEEE Standard 1149.1* expects the value on TDI to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDI pin is enabled after reset. Changes to the pull-up resistor settings on GPIO Port C should ensure that the internal pull-up resistor remains enabled on PC2/TDI; otherwise JTAG communication could be lost.

5.2.1.4 Test Data Output (TDO)

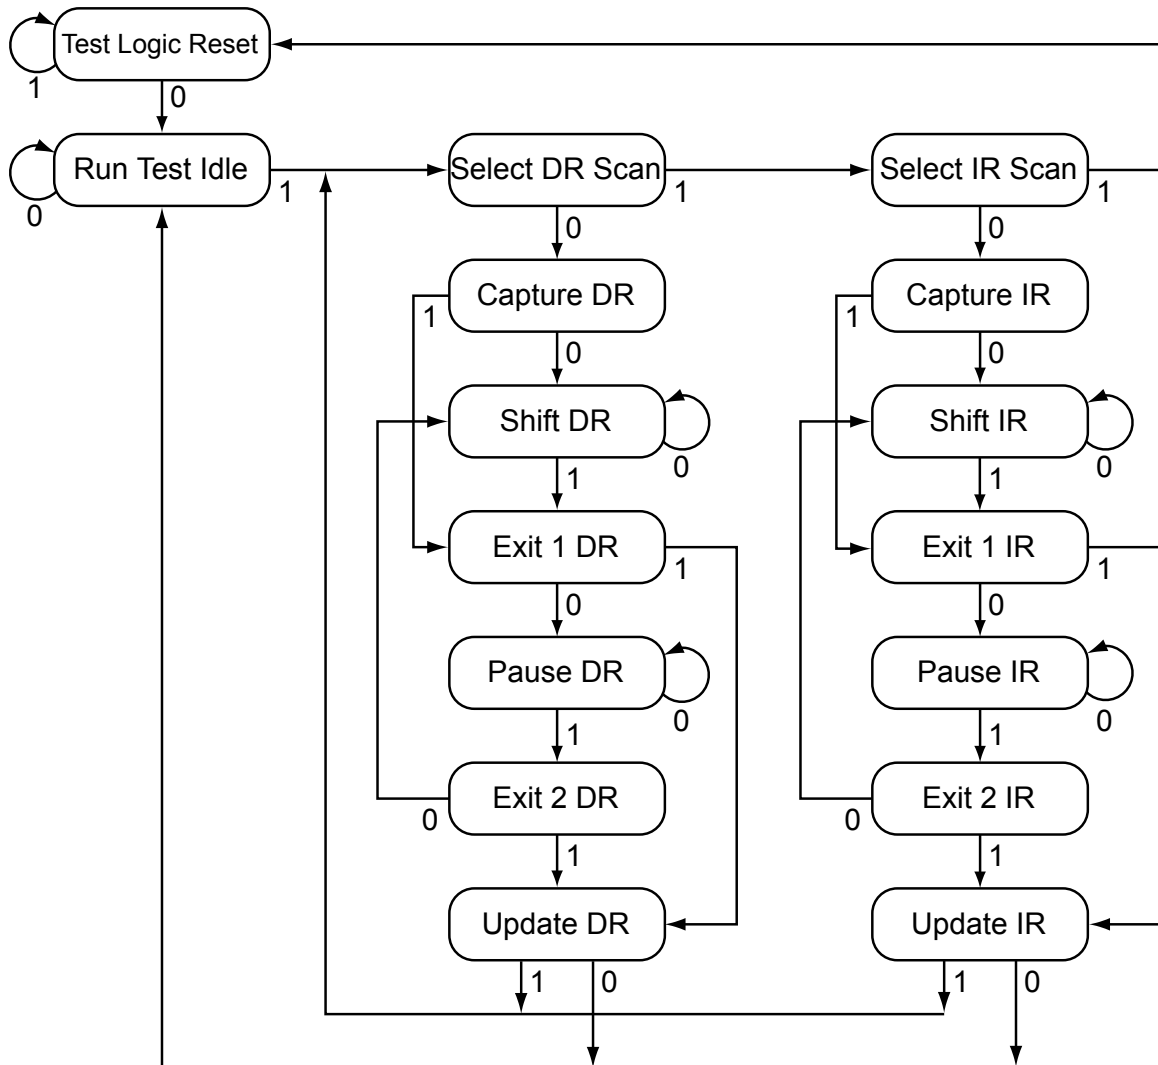

The TDO pin provides an output stream of serial information from the IR chain or the DR chains. The value of TDO depends on the current TAP state, the current instruction, and the data in the chain being accessed. In order to save power when the JTAG port is not being used, the TDO pin is placed in an inactive drive state when not actively shifting out data. Because TDO can be connected to the TDI of another controller in a daisy-chain configuration, the *IEEE Standard 1149.1* expects the value on TDO to change on the falling edge of TCK.

By default, the internal pull-up resistor on the TDO pin is enabled after reset. This assures that the pin remains at a constant logic level when the JTAG port is not being used. The internal pull-up and pull-down resistors can be turned off to save internal power if a High-Z output value is acceptable during certain TAP controller states.

5.2.2 JTAG TAP Controller

The JTAG TAP controller state machine is shown in Figure 5-2 on page 55. The TAP controller state machine is reset to the Test-Logic-Reset state on the assertion of a Power-On-Reset (POR). Asserting the correct sequence on the TMS pin allows the JTAG module to shift in new instructions, shift in data, or idle during extended testing sequences. For detailed information on the function of the TAP controller and the operations that occur in each state, please refer to *IEEE Standard 1149.1*.

Figure 5-2. Test Access Port State Machine

5.2.3 Shift Registers

The Shift Registers consist of a serial shift register chain and a parallel load register. The serial shift register chain samples specific information during the TAP controller's CAPTURE states and allows this information to be shifted out of TDO during the TAP controller's SHIFT states. While the sampled data is being shifted out of the chain on TDO, new data is being shifted into the serial shift register on TDI. This new data is stored in the parallel load register during the TAP controller's UPDATE states. Each of the shift registers is discussed in detail in "Register Descriptions" on page 58.

5.2.4 Operational Considerations

There are certain operational considerations when using the JTAG module. Because the JTAG pins can be programmed to be GPIOs, board configuration and reset conditions on these pins must be considered. In addition, because the JTAG module has integrated ARM Serial Wire Debug, the method for switching between these two operational modes is described below.

5.2.4.1 GPIO Functionality

When the controller is reset with either a POR or $\overline{\text{RST}}$, the JTAG/SWD port pins default to their JTAG/SWD configurations. The default configuration includes enabling digital functionality (setting **GPIODEN** to 1), enabling the pull-up resistors (setting **GPIOPUR** to 1), and enabling the alternate hardware function (setting **GPIOAFSEL** to 1) for the PC[3:0] JTAG/SWD pins.

It is possible for software to configure these pins as GPIOs after reset by writing 0s to PC[3:0] in the **GPIOAFSEL** register. If the user does not require the JTAG/SWD port for debugging or board-level testing, this provides four more GPIOs for use in the design.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. This may lock the debugger out of the part. This can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 235), **GPIO Pull-Up Select (GPIOPUR)** register (see page 241), and **GPIO Digital Enable (GPIODEN)** register (see page 244) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 246) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 247) have been set to 1.

Recovering a "Locked" Device

Note: Performing the below sequence will cause the nonvolatile registers discussed in “Nonvolatile Register Programming” on page 130 to be restored to their factory default values. The mass erase of the flash memory caused by the below sequence occurs prior to the nonvolatile registers being restored.

If software configures any of the JTAG/SWD pins as GPIO and loses the ability to communicate with the debugger, there is a debug sequence that can be used to recover the device. Performing a total of ten JTAG-to-SWD and SWD-to-JTAG switch sequences while holding the device in reset mass erases the flash memory. The sequence to recover the device is:

1. Assert and hold the $\overline{\text{RST}}$ signal.
2. Perform the JTAG-to-SWD switch sequence.
3. Perform the SWD-to-JTAG switch sequence.
4. Perform the JTAG-to-SWD switch sequence.
5. Perform the SWD-to-JTAG switch sequence.
6. Perform the JTAG-to-SWD switch sequence.
7. Perform the SWD-to-JTAG switch sequence.
8. Perform the JTAG-to-SWD switch sequence.
9. Perform the SWD-to-JTAG switch sequence.
10. Perform the JTAG-to-SWD switch sequence.

11. Perform the SWD-to-JTAG switch sequence.
12. Release the $\overline{\text{RST}}$ signal.
13. Wait 400 ms.
14. Power-cycle the device.

The JTAG-to-SWD and SWD-to-JTAG switch sequences are described in “ARM Serial Wire Debug (SWD)” on page 57. When performing switch sequences for the purpose of recovering the debug capabilities of the device, only steps 1 and 2 of the switch sequence need to be performed.

5.2.4.2 ARM Serial Wire Debug (SWD)

In order to seamlessly integrate the ARM Serial Wire Debug (SWD) functionality, a serial-wire debugger must be able to connect to the Cortex-M3 core without having to perform, or have any knowledge of, JTAG cycles. This is accomplished with a SWD preamble that is issued before the SWD session begins.

The preamble used to enable the SWD interface of the SWJ-DP module starts with the TAP controller in the Test-Logic-Reset state. From here, the preamble sequences the TAP controller through the following states: Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, Test Logic Reset, Test Logic Reset, Run Test Idle, Run Test Idle, Select DR, Select IR, and Test Logic Reset states.

Stepping through this sequences of the TAP state machine enables the SWD interface and disables the JTAG interface. For more information on this operation and the SWD interface, see the *ARM® Cortex™-M3 Technical Reference Manual* and the *ARM® CoreSight Technical Reference Manual*.

Because this sequence is a valid series of JTAG operations that could be issued, the ARM JTAG TAP controller is not fully compliant to the *IEEE Standard 1149.1*. This is the only instance where the ARM JTAG TAP controller does not meet full compliance with the specification. Due to the low probability of this sequence occurring during normal operation of the TAP controller, it should not affect normal performance of the JTAG interface.

JTAG-to-SWD Switching

To switch the operating mode of the Debug Access Port (DAP) from JTAG to SWD mode, the external debug hardware must send a switch sequence to the device. The 16-bit switch sequence for switching to SWD mode is defined as b1110011110011110, transmitted LSB first. This can also be represented as 16'hE79E when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit JTAG-to-SWD switch sequence, 16'hE79E.
3. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that if SWJ-DP was already in SWD mode, before sending the switch sequence, the SWD goes into the line reset state.

SWD-to-JTAG Switching

To switch the operating mode of the Debug Access Port (DAP) from SWD to JTAG mode, the external debug hardware must send a switch sequence to the device. The 16-bit switch sequence for switching to JTAG mode is defined as b1110011110011110, transmitted LSB first. This can also

be represented as 16'hE73C when transmitted LSB first. The complete switch sequence should consist of the following transactions on the TCK/SWCLK and TMS/SWDIO signals:

1. Send at least 50 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that both JTAG and SWD are in their reset/idle states.
2. Send the 16-bit SWD-to-JTAG switch sequence, 16'hE73C.
3. Send at least 5 TCK/SWCLK cycles with TMS/SWDIO set to 1. This ensures that if SWJ-DP was already in JTAG mode, before sending the switch sequence, the JTAG goes into the Test Logic Reset state.

5.3 Initialization and Configuration

After a Power-On-Reset or an external reset (\overline{RST}), the JTAG pins are automatically configured for JTAG communication. No user-defined initialization or configuration is needed. However, if the user application changes these pins to their GPIO function, they must be configured back to their JTAG functionality before JTAG communication can be restored. This is done by enabling the four JTAG pins ($PC[3:0]$) for their alternate function using the **GPIOAFSEL** register.

5.4 Register Descriptions

There are no APB-accessible registers in the JTAG TAP Controller or Shift Register chains. The registers within the JTAG controller are all accessed serially through the TAP Controller. The registers can be broken down into two main categories: Instruction Registers and Data Registers.

5.4.1 Instruction Register (IR)

The JTAG TAP Instruction Register (IR) is a four-bit serial scan chain with a parallel load register connected between the JTAG TDI and TDO pins. When the TAP Controller is placed in the correct states, bits can be shifted into the Instruction Register. Once these bits have been shifted into the chain and updated, they are interpreted as the current instruction. The decode of the Instruction Register bits is shown in Table 5-2 on page 58. A detailed explanation of each instruction, along with its associated Data Register, follows.

Table 5-2. JTAG Instruction Register Commands

IR[3:0]	Instruction	Description
0000	EXTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction onto the pads.
0001	INTEST	Drives the values preloaded into the Boundary Scan Chain by the SAMPLE/PRELOAD instruction into the controller.
0010	SAMPLE / PRELOAD	Captures the current I/O values and shifts the sampled values out of the Boundary Scan Chain while new preload data is shifted in.
1000	ABORT	Shifts data into the ARM Debug Port Abort Register.
1010	DPACC	Shifts data into and out of the ARM DP Access Register.
1011	APACC	Shifts data into and out of the ARM AC Access Register.
1110	IDCODE	Loads manufacturing information defined by the <i>IEEE Standard 1149.1</i> into the IDCODE chain and shifts it out.
1111	BYPASS	Connects TDI to TDO through a single Shift Register chain.
All Others	Reserved	Defaults to the BYPASS instruction to ensure that TDI is always connected to TDO.

5.4.1.1 EXTEST Instruction

The EXTEST instruction does not have an associated Data Register chain. The EXTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the EXTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the outputs and output enables are used to drive the GPIO pads rather than the signals coming from the core. This allows tests to be developed that drive known values out of the controller, which can be used to verify connectivity.

5.4.1.2 INTEST Instruction

The INTEST instruction does not have an associated Data Register chain. The INTEST instruction uses the data that has been preloaded into the Boundary Scan Data Register using the SAMPLE/PRELOAD instruction. When the INTEST instruction is present in the Instruction Register, the preloaded data in the Boundary Scan Data Register associated with the inputs are used to drive the signals going into the core rather than the signals coming from the GPIO pads. This allows tests to be developed that drive known values into the controller, which can be used for testing.

5.4.1.3 SAMPLE/PRELOAD Instruction

The SAMPLE/PRELOAD instruction connects the Boundary Scan Data Register chain between TDI and TDO. This instruction samples the current state of the pad pins for observation and preloads new test data. Each GPIO pad has an associated input, output, and output enable signal. When the TAP controller enters the Capture DR state during this instruction, the input, output, and output-enable signals to each of the GPIO pads are captured. These samples are serially shifted out of TDO while the TAP controller is in the Shift DR state and can be used for observation or comparison in various tests.

While these samples of the inputs, outputs, and output enables are being shifted out of the Boundary Scan Data Register, new data is being shifted into the Boundary Scan Data Register from TDI. Once the new data has been shifted into the Boundary Scan Data Register, the data is saved in the parallel load registers when the TAP controller enters the Update DR state. This update of the parallel load register preloads data into the Boundary Scan Data Register that is associated with each input, output, and output enable. This preloaded data can be used with the EXTEST and INTEST instructions to drive data into or out of the controller. Please see “Boundary Scan Data Register” on page 61 for more information.

5.4.1.4 ABORT Instruction

The ABORT instruction connects the associated ABORT Data Register chain between TDI and TDO. This instruction provides read and write access to the ABORT Register of the ARM Debug Access Port (DAP). Shifting the proper data into this Data Register clears various error bits or initiates a DAP abort of a previous request. Please see the “ABORT Data Register” on page 62 for more information.

5.4.1.5 DPACC Instruction

The DPACC instruction connects the associated DPACC Data Register chain between TDI and TDO. This instruction provides read and write access to the DPACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to the ARM debug and status registers. Please see “DPACC Data Register” on page 61 for more information.

5.4.1.6 APACC Instruction

The APACC instruction connects the associated APACC Data Register chain between TDI and TDO. This instruction provides read and write access to the APACC Register of the ARM Debug Access Port (DAP). Shifting the proper data into this register and reading the data output from this register allows read and write access to internal components and buses through the Debug Port. Please see “APACC Data Register” on page 61 for more information.

5.4.1.7 IDCODE Instruction

The IDCODE instruction connects the associated IDCODE Data Register chain between TDI and TDO. This instruction provides information on the manufacturer, part number, and version of the ARM core. This information can be used by testing equipment and debuggers to automatically configure their input and output data streams. IDCODE is the default instruction that is loaded into the JTAG Instruction Register when a power-on-reset (POR) is asserted, or the Test-Logic-Reset state is entered. Please see “IDCODE Data Register” on page 60 for more information.

5.4.1.8 BYPASS Instruction

The BYPASS instruction connects the associated BYPASS Data Register chain between TDI and TDO. This instruction is used to create a minimum length serial path between the TDI and TDO ports. The BYPASS Data Register is a single-bit shift register. This instruction improves test efficiency by allowing components that are not needed for a specific test to be bypassed in the JTAG scan chain by loading them with the BYPASS instruction. Please see “BYPASS Data Register” on page 61 for more information.

5.4.2 Data Registers

The JTAG module contains six Data Registers. These include: IDCODE, BYPASS, Boundary Scan, APACC, DPACC, and ABORT serial Data Register chains. Each of these Data Registers is discussed in the following sections.

5.4.2.1 IDCODE Data Register

The format for the 32-bit IDCODE Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-3 on page 60. The standard requires that every JTAG-compliant device implement either the IDCODE instruction or the BYPASS instruction as the default instruction. The LSB of the IDCODE Data Register is defined to be a 1 to distinguish it from the BYPASS instruction, which has an LSB of 0. This allows auto configuration test tools to determine which instruction is the default instruction.

The major uses of the JTAG port are for manufacturer testing of component assembly, and program development and debug. To facilitate the use of auto-configuration debug tools, the IDCODE instruction outputs a value of 0x3BA00477. This value indicates an ARM Cortex-M3, Version 1 processor. This allows the debuggers to automatically configure themselves to work correctly with the Cortex-M3 during debug.

Figure 5-3. IDCODE Register Format

5.4.2.2 BYPASS Data Register

The format for the 1-bit BYPASS Data Register defined by the *IEEE Standard 1149.1* is shown in Figure 5-4 on page 61. The standard requires that every JTAG-compliant device implement either the BYPASS instruction or the IDCODE instruction as the default instruction. The LSB of the BYPASS Data Register is defined to be a 0 to distinguish it from the IDCODE instruction, which has an LSB of 1. This allows auto configuration test tools to determine which instruction is the default instruction.

Figure 5-4. BYPASS Register Format

5.4.2.3 Boundary Scan Data Register

The format of the Boundary Scan Data Register is shown in Figure 5-5 on page 61. Each GPIO pin, in a counter-clockwise direction from the JTAG port pins, is included in the Boundary Scan Data Register. Each GPIO pin has three associated digital signals that are included in the chain. These signals are input, output, and output enable, and are arranged in that order as can be seen in the figure. In addition to the GPIO pins, the controller reset pin, $\overline{\text{RST}}$, is included in the chain. Because the reset pin is always an input, only the input signal is included in the Data Register chain.

When the Boundary Scan Data Register is accessed with the SAMPLE/PRELOAD instruction, the input, output, and output enable from each digital pad are sampled and then shifted out of the chain to be verified. The sampling of these values occurs on the rising edge of TCK in the Capture DR state of the TAP controller. While the sampled data is being shifted out of the Boundary Scan chain in the Shift DR state of the TAP controller, new data can be preloaded into the chain for use with the EXTEST and INTEST instructions. These instructions either force data out of the controller, with the EXTEST instruction, or into the controller, with the INTEST instruction.

Figure 5-5. Boundary Scan Register Format

For detailed information on the order of the input, output, and output enable bits for each of the GPIO ports, please refer to the Stellaris® Family Boundary Scan Description Language (BSDL) files, downloadable from www.luminarymicro.com.

5.4.2.4 APACC Data Register

The format for the 35-bit APACC Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

5.4.2.5 DPACC Data Register

The format for the 35-bit DPACC Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

5.4.2.6 ABORT Data Register

The format for the 35-bit ABORT Data Register defined by ARM is described in the *ARM® Cortex™-M3 Technical Reference Manual*.

6 System Control

System control determines the overall operation of the device. It provides information about the device, controls the clocking to the core and individual peripherals, and handles reset detection and reporting.

6.1 Functional Description

The System Control module provides the following capabilities:

- Device identification, see “Device Identification” on page 63
- Local control, such as reset (see “Reset Control” on page 63), power (see “Power Control” on page 66) and clock control (see “Clock Control” on page 66)
- System control (Run, Sleep, and Deep-Sleep modes), see “System Control” on page 70

6.1.1 Device Identification

Seven read-only registers provide software with information on the microcontroller, such as version, part number, SRAM size, flash size, and other features. See the **DID0**, **DID1**, and **DC0-DC7** registers.

6.1.2 Reset Control

This section discusses aspects of hardware functions during reset as well as system software requirements following the reset sequence.

6.1.2.1 Reset Sources

The controller has six sources of reset:

1. External reset input pin ($\overline{\text{RST}}$) assertion, see “ $\overline{\text{RST}}$ Pin Assertion” on page 63.
2. Power-on reset (POR), see “Power-On Reset (POR)” on page 64.
3. Internal brown-out (BOR) detector, see “Brown-Out Reset (BOR)” on page 64.
4. Software-initiated reset (with the software reset registers), see “Software Reset” on page 65.
5. A watchdog timer reset condition violation, see “Watchdog Timer Reset” on page 65.
6. MOSC failure

After a reset, the **Reset Cause (RESC)** register is set with the reset cause. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an internal POR is the cause, and then all the other bits in the **RESC** register are cleared except for the POR indicator.

6.1.2.2 $\overline{\text{RST}}$ Pin Assertion

The external reset pin ($\overline{\text{RST}}$) resets the controller. This resets the core and all the peripherals except the JTAG TAP controller (see “JTAG Interface” on page 51). The external reset sequence is as follows:

1. The external reset pin ($\overline{\text{RST}}$) is asserted and then de-asserted.

2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution. A few clocks cycles from $\overline{\text{RST}}$ de-assertion to the start of the reset sequence is necessary for synchronization.

The external reset timing is shown in Figure 22-8 on page 580.

6.1.2.3 Power-On Reset (POR)

The Power-On Reset (POR) circuit monitors the power supply voltage (V_{DD}). The POR circuit generates a reset signal to the internal logic when the power supply ramp reaches a threshold value (V_{TH}). If the application only uses the POR circuit, the $\overline{\text{RST}}$ input needs to be connected to the power supply (V_{DD}) through a pull-up resistor (1K to 10K Ω).

The device must be operating within the specified operating parameters at the point when the on-chip power-on reset pulse is complete. The 3.3-V power supply to the device must reach 3.0 V within 10 msec of it crossing 2.0 V to guarantee proper operation. For applications that require the use of an external reset to hold the device in reset longer than the internal POR, the $\overline{\text{RST}}$ input may be used with the circuit as shown in Figure 6-1 on page 64.

Figure 6-1. External Circuitry to Extend Reset

The R_1 and C_1 components define the power-on delay. The R_2 resistor mitigates any leakage from the $\overline{\text{RST}}$ input. The diode (D_1) discharges C_1 rapidly when the power supply is turned off.

The Power-On Reset sequence is as follows:

1. The controller waits for the later of external reset ($\overline{\text{RST}}$) or internal POR to go inactive.
2. The internal reset is released and the core loads from memory the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The internal POR is only active on the initial power-up of the controller. The Power-On Reset timing is shown in Figure 22-9 on page 580.

Note: The power-on reset also resets the JTAG controller. An external reset does not.

6.1.2.4 Brown-Out Reset (BOR)

A drop in the input voltage resulting in the assertion of the internal brown-out detector can be used to reset the controller. This is initially disabled and may be enabled by software.

The system provides a brown-out detection circuit that triggers if the power supply (V_{DD}) drops below a brown-out threshold voltage (V_{BTH}). If a brown-out condition is detected, the system may generate a controller interrupt or a system reset.

Brown-out resets are controlled with the **Power-On and Brown-Out Reset Control (PBORCTL)** register. The `BORIOR` bit in the **PBORCTL** register must be set for a brown-out condition to trigger a reset.

The brown-out reset is equivalent to an assertion of the external \overline{RST} input and the reset is held active until the proper V_{DD} level is restored. The **RESC** register can be examined in the reset interrupt handler to determine if a Brown-Out condition was the cause of the reset, thus allowing software to determine what actions are required to recover.

The internal Brown-Out Reset timing is shown in Figure 22-10 on page 581.

6.1.2.5 Software Reset

Software can reset a specific peripheral or generate a reset to the entire system .

Peripherals can be individually reset by software via three registers that control reset signals to each peripheral (see the **SRCRn** registers). If the bit position corresponding to a peripheral is set and subsequently cleared, the peripheral is reset. The encoding of the reset registers is consistent with the encoding of the clock gating control for peripherals and on-chip functions (see “System Control” on page 70). Note that all reset signals for all clocks of the specified unit are asserted as a result of a software-initiated reset.

The entire system can be reset by software by setting the `SYSRESETREQ` bit in the Cortex-M3 Application Interrupt and Reset Control register resets the entire system including the core. The software-initiated system reset sequence is as follows:

1. A software system reset is initiated by writing the `SYSRESETREQ` bit in the ARM Cortex-M3 Application Interrupt and Reset Control register.
2. An internal reset is asserted.
3. The internal reset is deasserted and the controller loads from memory the initial stack pointer, the initial program counter, and the first instruction designated by the program counter, and then begins execution.

The software-initiated system reset timing is shown in Figure 22-11 on page 581.

6.1.2.6 Watchdog Timer Reset

The watchdog timer module's function is to prevent system hangs. The watchdog timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out.

After the first time-out event, the 32-bit counter is reloaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled, the watchdog timer asserts its reset signal to the system. The watchdog timer reset sequence is as follows:

1. The watchdog timer times out for the second time without being serviced.
2. An internal reset is asserted.
3. The internal reset is released and the controller loads from memory the initial stack pointer, the initial program counter, the first instruction designated by the program counter, and begins execution.

The watchdog reset timing is shown in Figure 22-12 on page 581.

6.1.3 Non-Maskable Interrupt

The controller has two sources of non-maskable interrupt (NMI):

- The assertion of the NMI signal.
- A main oscillator verification error.

If both sources of NMI are enabled, software must check that the main oscillator verification is the cause of the interrupt in order to distinguish between the two sources.

6.1.3.1 NMI Pin

The alternate function to GPIO port pin B7 is an NMI signal. The alternate function must be enabled in the GPIO for the signal to be used as an interrupt, as described in “General-Purpose Input/Outputs (GPIOs)” on page 217. Note that enabling the NMI alternate function requires the use of the GPIO lock and commit function just like the GPIO port pins associated with JTAG/SWD functionality. The active sense of the NMI signal is High; asserting the enabled NMI signal above V_{IH} initiates the NMI interrupt sequence.

6.1.3.2 Main Oscillator Verification Failure

The main oscillator verification circuit may generate a reset event and then, during the subsequent POR, control is transferred to the NMI handler. The detection circuit is enabled using the CVAL bit in the **Main Oscillator Control (MOSCCTL)** register. The main oscillator verification error is indicated in the main oscillator fail status bit (MOSCFAIL bit in the **Reset Cause (RESC)** register. The main oscillator verification circuit action is described in more detail in “Clock Control” on page 66.

6.1.4 Power Control

The Stellaris[®] microcontroller provides an integrated LDO regulator that may be used to provide power to the majority of the controller’s internal logic. The LDO regulator provides software a mechanism to adjust the regulated value, in small increments (VSTEP), over the range of 2.25 V to 2.75 V (inclusive)—or $2.5\text{ V} \pm 10\%$. The adjustment is made by changing the value of the VADJ field in the **LDO Power Control (LDOPCTL)** register.

Note: On the printed circuit board, use the LDO output as the source of VDD25 input. In addition, the LDO requires decoupling capacitors. See “On-Chip Low Drop-Out (LDO) Regulator Characteristics” on page 572.

6.1.5 Clock Control

System control determines the control of clocks in this part.

6.1.5.1 Fundamental Clock Sources

There are four clock sources for use in the device:

- **Internal Oscillator (IOSC):** The internal oscillator is an on-chip clock source. It does not require the use of any external components. The frequency of the internal oscillator is $12\text{ MHz} \pm 30\%$. Applications that do not depend on accurate clock sources may use this clock source to reduce system cost. The internal oscillator is the clock source the device uses during and following POR. If the main oscillator is required, software must enable the main oscillator following reset and allow the main oscillator to stabilize before changing the clock reference.

- **Main Oscillator (MOSC):** The main oscillator provides a frequency-accurate clock source by one of two means: an external single-ended clock source is connected to the `OSC0` input pin, or an external crystal is connected across the `OSC0` input and `OSC1` output pins. If the PLL is being used, the crystal value must be one of the supported frequencies between 3.579545 MHz through 16.384 MHz (inclusive). If the PLL is not being used, the crystal may be any one of the supported frequencies between 1 MHz and 16.384 MHz. The single-ended clock source range is from DC through the specified speed of the device. The supported crystals are listed in the `XTAL` bit field in the **RCC** register (see page 81).
- **Internal 30-kHz Oscillator:** The internal 30-kHz oscillator is similar to the internal oscillator, except that it provides an operational frequency of 30 kHz \pm 50%. It is intended for use during Deep-Sleep power-saving modes. This power-savings mode benefits from reduced internal switching and also allows the main oscillator to be powered down.

The internal system clock (SysClk), is derived from any of the four sources plus two others: the output of the main internal PLL, and the internal oscillator divided by four (3 MHz \pm 30%). The frequency of the PLL clock reference must be in the range of 3.579545 MHz to 16.384 MHz (inclusive).

The **Run-Mode Clock Configuration (RCC)** and **Run-Mode Clock Configuration 2 (RCC2)** registers provide control for the system clock. The **RCC2** register is provided to extend fields that offer additional encodings over the **RCC** register. When used, the **RCC2** register field values are used by the logic over the corresponding field in the **RCC** register. In particular, **RCC2** provides for a larger assortment of clock configuration options.

Figure 6-2 on page 68 shows the logic for the main clock tree. The peripheral blocks are driven by the system clock signal and can be programmatically enabled/disabled. The ADC clock signal is automatically divided down to 16 MHz for proper ADC operation. The PWM clock signal is a synchronous divide by of the system clock to provide the PWM circuit with more range.

Figure 6-2. Main Clock Tree

- a. Control provided by RCC register bit/field.
 b. Control provided by RCC register bit/field or RCC2 register bit/field, if overridden with RCC2 register bit USERCC2.
 c. Control provided by RCC2 register bit/field.
 d. Also may be controlled by DSLPCLKCFG when in deep sleep mode.

Note: The figure above shows all features available on all Stellaris® DustDevil-class devices.

6.1.5.2 Crystal Configuration for the Main Oscillator (MOSC)

The main oscillator supports the use of a select number of crystals. If the main oscillator is used by the PLL as a reference clock, the supported range of crystals is 3.579545 to 16.384 MHz, otherwise, the range of supported crystals is 1 to 16.384 MHz.

The XTAL bit in the **RCC** register (see page 81) describes the available crystal choices and default programming values.

Software configures the **RCC** register `XTAL` field with the crystal number. If the PLL is used in the design, the `XTAL` field value is internally translated to the PLL settings.

6.1.5.3 Main PLL Frequency Configuration

The main PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency, and enables the main PLL to drive the output.

If the main oscillator provides the clock reference to the main PLL, the translation provided by hardware and used to program the PLL is available for software in the **XTAL to PLL Translation (PLLCFG)** register (see page 86). The internal translation provides a translation within $\pm 1\%$ of the targeted PLL VCO frequency.

The Crystal Value field (`XTAL`) on page 81 describes the available crystal choices and default programming of the **PLLCFG** register. The crystal number is written into the `XTAL` field of the **Run-Mode Clock Configuration (RCC)** register. Any time the `XTAL` field changes, the new settings are translated and the internal PLL settings are updated.

6.1.5.4 PLL Modes

The PLL has two modes of operation: Normal and Power-Down

- Normal: The PLL multiplies the input clock reference and drives the output.
- Power-Down: Most of the PLL internal circuitry is disabled and the PLL does not drive the output.

The modes are programmed using the **RCC/RCC2** register fields (see page 81 and page 88).

6.1.5.5 PLL Operation

If a PLL configuration is changed, the PLL output frequency is unstable until it reconverges (relocks) to the new setting. The time between the configuration change and relock is T_{READY} (see Table 22-6 on page 574). During the relock time, the affected PLL is not usable as a clock reference.

The PLL is changed by one of the following:

- Change to the `XTAL` value in the **RCC** register—writes of the same value do not cause a relock.
- Change in the PLL from Power-Down to Normal mode.

A counter is defined to measure the T_{READY} requirement. The counter is clocked by the main oscillator. The range of the main oscillator has been taken into account and the down counter is set to 0x1200 (that is, $\sim 600 \mu\text{s}$ at an 8.192 MHz external oscillator clock). When the `XTAL` value is greater than 0x0f, the down counter is set to 0x2400 to maintain the required lock time on higher frequency crystal inputs. Hardware is provided to keep the PLL from being used as a system clock until the T_{READY} condition is met after one of the two changes above. It is the user's responsibility to have a stable clock source (like the main oscillator) before the **RCC/RCC2** register is switched to use the PLL.

If the main PLL is enabled and the system clock is switched to use the PLL in one step, the system control hardware continues to clock the controller from the oscillator selected by the **RCC/RCC2** register until the main PLL is stable (T_{READY} time met), after which it changes to the PLL. Software can use many methods to ensure that the system is clocked from the main PLL, including periodically polling the `PLLRLIS` bit in the **Raw Interrupt Status (RIS)** register, and enabling the PLL Lock interrupt.

6.1.5.6 Main Oscillator Verification Circuit

A circuit is added to ensure that the main oscillator is running at the appropriate frequency. The circuit monitors the main oscillator frequency and signals if the frequency is outside of the allowable band of attached crystals.

The detection circuit is enabled using the `CVAL` bit in the **Main Oscillator Control (MOSCCTL)** register. If this circuit is enabled and detects an error, the following sequence is performed by the hardware:

1. The `MOSCFAIL` bit in the **Reset Cause (RESC)** register is set.
2. If the internal oscillator (IOSC) is disabled, it is enabled.
3. The system clock is switched from the main oscillator to the IOSC.
4. A system-wide reset is initiated that lasts for 32 IOSC periods.
5. Reset is de-asserted and the processor is directed to the NMI handler during the reset sequence.

6.1.6 System Control

For power-savings purposes, the **RCGCn**, **SCGCn**, and **DCGCn** registers control the clock gating logic for each peripheral or block in the system while the controller is in Run, Sleep, and Deep-Sleep mode, respectively.

In Run mode, the processor executes code. In Sleep mode, the clock frequency of the active peripherals is unchanged, but the processor is not clocked and therefore no longer executes code. In Deep-Sleep mode, the clock frequency of the active peripherals may change (depending on the Run mode clock configuration) in addition to the processor clock being stopped. An interrupt returns the device to Run mode from one of the sleep modes; the sleep modes are entered on request from the code. Each mode is described in more detail below.

There are four levels of operation for the device defined as:

- **Run Mode.** Run mode provides normal operation of the processor and all of the peripherals that are currently enabled by the **RCGCn** registers. The system clock can be any of the available clock sources including the PLL.
- **Sleep Mode.** Sleep mode is entered by the Cortex-M3 core executing a `WFI` (Wait for Interrupt) instruction. Any properly configured interrupt event in the system will bring the processor back into Run mode. See the system control NVIC section of the *ARM® Cortex™-M3 Technical Reference Manual* for more details.

In Sleep mode, the Cortex-M3 processor core and the memory subsystem are not clocked. Peripherals are clocked that are enabled in the **SCGCn** register when auto-clock gating is enabled (see the **RCC** register) or the **RCGCn** register when the auto-clock gating is disabled. The system clock has the same source and frequency as that during Run mode.

- **Deep-Sleep Mode.** Deep-Sleep mode is entered by first writing the Deep Sleep Enable bit in the ARM Cortex-M3 NVIC system control register and then executing a `WFI` instruction. Any properly configured interrupt event in the system will bring the processor back into Run mode. See the system control NVIC section of the *ARM® Cortex™-M3 Technical Reference Manual* for more details.

The Cortex-M3 processor core and the memory subsystem are not clocked. Peripherals are clocked that are enabled in the **DCGCn** register when auto-clock gating is enabled (see the **RCC**

register) or the **RCCn** register when auto-clock gating is disabled. The system clock source is the main oscillator by default or the internal oscillator specified in the **DSLPCCLKCFG** register if one is enabled. When the **DSLPCCLKCFG** register is used, the internal oscillator is powered up, if necessary, and the main oscillator is powered down. If the PLL is running at the time of the WFI instruction, hardware will power the PLL down and override the **SYSDIV** field of the active **RCC/RCC2** register to be /16 or /64, respectively. When the Deep-Sleep exit event occurs, hardware brings the system clock back to the source and frequency it had at the onset of Deep-Sleep mode before enabling the clocks that had been stopped during the Deep-Sleep duration.

6.2 Initialization and Configuration

The PLL is configured using direct register writes to the **RCC/RCC2** register. If the **RCC2** register is being used, the **USERCC2** bit must be set and the appropriate **RCC2** bit/field is used. The steps required to successfully change the PLL-based system clock are:

1. Bypass the PLL and system clock divider by setting the **BYPASS** bit and clearing the **USESYS** bit in the **RCC** register. This configures the system to run off a “raw” clock source (using the main oscillator or internal oscillator) and allows for the new PLL configuration to be validated before switching the system clock to the PLL.
2. Select the crystal value (**XTAL**) and oscillator source (**OSCSRC**), and clear the **PWRDN** bit in **RCC/RCC2**. Setting the **XTAL** field automatically pulls valid PLL configuration data for the appropriate crystal, and clearing the **PWRDN** bit powers and enables the PLL and its output.
3. Select the desired system divider (**SYSDIV**) in **RCC/RCC2** and set the **USESYS** bit in **RCC**. The **SYSDIV** field determines the system frequency for the microcontroller.
4. Wait for the PLL to lock by polling the **PLLLRIS** bit in the **Raw Interrupt Status (RIS)** register.
5. Enable use of the PLL by clearing the **BYPASS** bit in **RCC/RCC2**.

6.3 Register Map

Table 6-1 on page 71 lists the System Control registers, grouped by function. The offset listed is a hexadecimal increment to the register’s address, relative to the System Control base address of 0x400F.E000.

Note: Spaces in the System Control register space that are not used are reserved for future or internal use by Luminary Micro, Inc. Software should not modify any reserved memory address.

Note: Additional Flash and ROM registers defined in the System Control register space are described in the “Internal Memory” on page 127.

Table 6-1. System Control Register Map

Bit/Field	Name	Type	Reset	Description				
31	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
30:28	VER	RO	0x1	<p>DID0 Version</p> <p>This field defines the DID0 register format version. The version number is numeric. The value of the <code>VER</code> field is encoded as follows:</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x1</td> <td>Second version of the DID0 register format.</td> </tr> </tbody> </table>	Value	Description	0x1	Second version of the DID0 register format.
Value	Description							
0x1	Second version of the DID0 register format.							
27:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.				
23:16	CLASS	RO	0x3	<p>Device Class</p> <p>The <code>CLASS</code> field value identifies the internal design from which all mask sets are generated for all devices in a particular product line. The <code>CLASS</code> field value is changed for new product lines, for changes in fab process (for example, a remap or shrink), or any case where the <code>MAJOR</code> or <code>MINOR</code> fields require differentiation from prior devices. The value of the <code>CLASS</code> field is encoded as follows (all other encodings are reserved):</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x3</td> <td>Stellaris® DustDevil-class devices</td> </tr> </tbody> </table>	Value	Description	0x3	Stellaris® DustDevil-class devices
Value	Description							
0x3	Stellaris® DustDevil-class devices							

Bit/Field	Name	Type	Reset	Description								
15:8	MAJOR	RO	-	<p>Major Revision</p> <p>This field specifies the major revision number of the device. The major revision reflects changes to base layers of the design. The major revision number is indicated in the part number as a letter (A for first revision, B for second, and so on). This field is encoded as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Revision A (initial device)</td></tr><tr><td>0x1</td><td>Revision B (first base layer revision)</td></tr><tr><td>0x2</td><td>Revision C (second base layer revision)</td></tr></tbody></table> <p>and so on.</p>	Value	Description	0x0	Revision A (initial device)	0x1	Revision B (first base layer revision)	0x2	Revision C (second base layer revision)
Value	Description											
0x0	Revision A (initial device)											
0x1	Revision B (first base layer revision)											
0x2	Revision C (second base layer revision)											
7:0	MINOR	RO	-	<p>Minor Revision</p> <p>This field specifies the minor revision number of the device. The minor revision reflects changes to the metal layers of the design. The <code>MINOR</code> field value is reset when the <code>MAJOR</code> field is changed. This field is numeric and is encoded as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0x0</td><td>Initial device, or a major revision update.</td></tr><tr><td>0x1</td><td>First metal layer change.</td></tr><tr><td>0x2</td><td>Second metal layer change.</td></tr></tbody></table> <p>and so on.</p>	Value	Description	0x0	Initial device, or a major revision update.	0x1	First metal layer change.	0x2	Second metal layer change.
Value	Description											
0x0	Initial device, or a major revision update.											
0x1	First metal layer change.											
0x2	Second metal layer change.											

Register 2: Brown-Out Reset Control (PBORCTL), offset 0x030

This register is responsible for controlling reset conditions after initial power-on reset.

Brown-Out Reset Control (PBORCTL)

Base 0x400F.E000

Offset 0x030

Type R/W, reset 0x0000.7FFD

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIOR	R/W	0	BOR Interrupt or Reset This bit controls how a BOR event is signaled to the controller. If set, a reset is signaled. Otherwise, an interrupt is signaled.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 3: LDO Power Control (LDOPCTL), offset 0x034

The V_{ADJ} field in this register adjusts the on-chip output voltage (V_{OUT}).

LDO Power Control (LDOPCTL)

Base 0x400F.E000
 Offset 0x034
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

5:0	VADJ	R/W	0x0	LDO Output Voltage
				This field sets the on-chip output voltage. The programming values for the V _{ADJ} field are provided below.

Value	V _{OUT} (V)
0x00	2.50
0x01	2.45
0x02	2.40
0x03	2.35
0x04	2.30
0x05	2.25
0x06-0x3F	Reserved
0x1B	2.75
0x1C	2.70
0x1D	2.65
0x1E	2.60
0x1F	2.55

Register 4: Raw Interrupt Status (RIS), offset 0x050

Central location for system control raw interrupts. These are set and cleared by hardware.

Raw Interrupt Status (RIS)

Base 0x400F.E000

Offset 0x050

Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPRIS	RO	0	MOSC Power Up Raw Interrupt Status This bit is set when the PLL $T_{MOSCPUP}$ Timer asserts.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLRIS	RO	0	PLL Lock Raw Interrupt Status This bit is set when the PLL T_{READY} Timer asserts.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORRIS	RO	0	Brown-Out Reset Raw Interrupt Status This bit is the raw interrupt status for any brown-out conditions. If set, a brown-out condition is currently active. This is an unregistered signal from the brown-out detection circuit. An interrupt is reported if the BORIM bit in the IMC register is set and the BORIOR bit in the PBORCTL register is cleared.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 5: Interrupt Mask Control (IMC), offset 0x054

Central location for system control interrupt masks.

Interrupt Mask Control (IMC)

Base 0x400F.E000
 Offset 0x054
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPIM	R/W	0	MOSC Power Up Interrupt Mask This bit specifies whether a current limit detection is promoted to a controller interrupt. If set, an interrupt is generated if MOSCPUPRIS in RIS is set; otherwise, an interrupt is not generated.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLIM	R/W	0	PLL Lock Interrupt Mask This bit specifies whether a current limit detection is promoted to a controller interrupt. If set, an interrupt is generated if PLLLRIS in RIS is set; otherwise, an interrupt is not generated.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORIM	R/W	0	Brown-Out Reset Interrupt Mask This bit specifies whether a brown-out condition is promoted to a controller interrupt. If set, an interrupt is generated if BORRIS is set; otherwise, an interrupt is not generated.
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 6: Masked Interrupt Status and Clear (MISC), offset 0x058

On a read, this register gives the current masked status value of the corresponding interrupt. All of the bits are R/W1C and this action also clears the corresponding raw interrupt bit in the **RIS** register (see page 77).

Masked Interrupt Status and Clear (MISC)

Base 0x400F.E000

Offset 0x058

Type R/W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:9	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
8	MOSCPUPMIS	R/W1C	0	MOSC Power Up Masked Interrupt Status This bit is set when the $T_{MOSCPUP}$ timer asserts. The interrupt is cleared by writing a 1 to this bit.
7	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	PLLLMIS	R/W1C	0	PLL Lock Masked Interrupt Status This bit is set when the PLL T_{READY} timer asserts. The interrupt is cleared by writing a 1 to this bit.
5:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	BORMIS	R/W1C	0	BOR Masked Interrupt Status The BORMIS is simply the BORRIS ANDed with the mask value, BORIM .
0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 7: Reset Cause (RESC), offset 0x05C

This register is set with the reset cause after reset. The bits in this register are sticky and maintain their state across multiple reset sequences, except when an external reset is the cause, and then all the other bits in the **RESC** register are cleared.

Reset Cause (RESC)

Base 0x400F.E000

Offset 0x05C

Type R/W, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	IOSCDIS	R/W	0	Internal Oscillator Disable 0: Internal oscillator (IOSC) is enabled. 1: Internal oscillator is disabled.
0	MOSCDIS	R/W	1	Main Oscillator Disable 0: Main oscillator is enabled . 1: Main oscillator is disabled (default).

Register 9: XTAL to PLL Translation (PLLCFG), offset 0x064

This register provides a means of translating external crystal frequencies into the appropriate PLL settings. This register is initialized during the reset sequence and updated anytime that the XTAL field changes in the Run-Mode Clock Configuration (RCC) register (see page 81).

The PLL frequency is calculated using the PLLCFG field values, as follows:

$$PLLFreq = OSCFreq * F / (R + 1)$$

XTAL to PLL Translation (PLLCFG)

Base 0x400F.E000

Offset 0x064

Type RO, reset -

Bit/Field	Name	Type	Reset	Description
31:14	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13:5	F	RO	-	PLL F Value This field specifies the value supplied to the PLL's F input.
4:0	R	RO	-	PLL R Value This field specifies the value supplied to the PLL's R input.

Register 10: GPIO High Speed Control (GPIOHSCTL), offset 0x06C

This register provides the user the ability to change the GPIO ports to run on a single-cycle bus equivalent to the processor clock instead of the legacy bus with two-cycle access. The address aperture in the memory map will change for the ports that are enabled for high-speed access (see Table 9-3 on page 224).

GPIO High Speed Control (GPIOHSCTL)

1	PORTBHS	R/W	0	Port B High-Speed When set, the memory aperture for Port H is selected to be high speed (single-cycle). Otherwise, the legacy aperture (two-cycle) is chosen.
0	PORTAHS	R/W	0	Port A High-Speed When set, the memory aperture for Port H is selected to be high speed (single-cycle). Otherwise, the legacy aperture (two-cycle) is chosen.

Register 11: Run-Mode Clock Configuration 2 (RCC2), offset 0x070

This register overrides the **RCC** equivalent register fields when the `USERCC2` bit is set. This allows **RCC2** to be used to extend the capabilities, while also providing a means to be backward-compatible to previous parts. The fields within the **RCC2** register occupy the same bit positions as they do within the **RCC** register as LSB-justified.

The `SYSDIV2` field is wider so that additional larger divisors are possible. This allows a lower system clock frequency for improved Deep Sleep power consumption.

Run-Mode Clock Configuration 2 (RCC2)

Base 0x400F.E000
 Offset 0x070
 Type R/W, reset 0x0780.6810

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31	USERCC2	R/W	0	Use RCC2 When set, overrides the RCC register fields.
30:29	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28:23	SYSDIV2	R/W	0x0F	System Clock Divisor Specifies which divisor is used to generate the system clock from the PLL output. The PLL VCO frequency is 400 MHz. This field is wider than the RCC register <code>SYSDIV</code> field in order to provide additional divisor values. This permits the system clock to be run at much lower frequencies during Deep Sleep mode. For example, where the RCC register <code>SYSDIV</code> encoding of 1111 provides /16, the RCC2 register <code>SYSDIV2</code> encoding of 111111 provides /64.
22:15	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14	reserved-1	RO	1	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. Note that reset value is 1.
13	PWRDN2	R/W	1	Power-Down PLL When set, powers down the PLL.

Bit/Field	Name	Type	Reset	Description												
12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.												
11	BYPASS2	R/W	1	Bypass PLL When set, bypasses the PLL for the clock source.												
10:7	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.												
6:4	OSCSRC2	R/W	0x1	Oscillator Source Picks among the input sources for the OSC. The values are: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Main oscillator (MOSC)</td> </tr> <tr> <td>0x1</td> <td>Internal oscillator (IOSC)</td> </tr> <tr> <td>0x2</td> <td>Internal oscillator / 4</td> </tr> <tr> <td>0x3</td> <td>30 kHz internal oscillator</td> </tr> <tr> <td>0x7</td> <td>Reserved</td> </tr> </tbody> </table>	Value	Description	0x0	Main oscillator (MOSC)	0x1	Internal oscillator (IOSC)	0x2	Internal oscillator / 4	0x3	30 kHz internal oscillator	0x7	Reserved
Value	Description															
0x0	Main oscillator (MOSC)															
0x1	Internal oscillator (IOSC)															
0x2	Internal oscillator / 4															
0x3	30 kHz internal oscillator															
0x7	Reserved															
3:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.												

Register 12: Main Oscillator Control (MOSCCTL), offset 0x07C

This register provides control over the features of the main oscillator, including the ability to enable the MOSC clock validation circuit. When enabled, this circuit monitors the energy on the MOSC pins to provide a Clock Valid signal. If the clock goes invalid after being enabled, the part does a hardware reset and reboots to the NMI handler.

Main Oscillator Control (MOSCCTL)

Base 0x400F.E000
 Offset 0x07C
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	CVAL	R/W	0	Clock Validation for MOSC When set, the monitor circuit is enabled.

Register 13: Deep Sleep Clock Configuration (DSLPCCLKCFG), offset 0x144

This register provides configuration information for the hardware control of Deep Sleep Mode.

Deep Sleep Clock Configuration (DSLPCCLKCFG)

Base 0x400F.E000
 Offset 0x144
 Type R/W, reset 0x0780.0000

Bit/Field	Name	Type	Reset	Description
31:29	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
28:23	DSDIVORIDE	R/W	0x0F	Divider Field Override 6-bit system divider field to override when Deep-Sleep occurs with PLL running.
22:7	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:4	DSOSCSRC	R/W	0x0	Clock Source Specifies the clock source during Deep-Sleep mode. Value Description 0x0 NOORIDE No override to the oscillator clock source is done. 0x1 IOSC Use internal 12 MHz oscillator as source. 0x3 30kHz Use 30 kHz internal oscillator. 0x7 Reserved
3:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 14: Device Identification 1 (DID1), offset 0x004

This register identifies the device family, part number, temperature range, and package type.

Device Identification 1 (DID1)

Base 0x400F.E000

Offset 0x004

Type RO, reset -

31:25	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
24	CAN0	RO	1	CAN Module 0 Present When set, indicates that CAN unit 0 is present.
23:21	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20	PWM	RO	1	PWM Module Present When set, indicates that the PWM module is present.
19:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	ADC	RO	1	ADC Module Present. When set, indicates that the ADC module is present.
15:12	MINSYSDIV	RO	0x3	System Clock Divider. Minimum 4-bit divider value for system clock. The reset value is hardware-dependent. See the RCC register for how to change the system clock divisor using the <code>SYSDIV</code> bit. Value Description 0x3 Specifies a 50-MHz CPU clock with a PLL divider of 4.
11:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
9:8	MAXADCSPD	RO	0x2	Max ADC Speed. This field indicates the maximum rate at which the ADC samples data. Value Description 0x2 500K samples/second
7	MPU	RO	1	MPU Present. When set, indicates that the Cortex-M3 Memory Protection Unit (MPU) module is present. See the ARM Cortex-M3 Technical Reference Manual for details on the MPU.
6	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	TEMPSNS	RO	1	Temp Sensor Present. When set, indicates that the on-chip temperature sensor is present.
4	PLL	RO	1	PLL Present. When set, indicates that the on-chip Phase Locked Loop (PLL) is present.
3	WDT	RO	1	Watchdog Timer Present. When set, indicates that a watchdog timer is present.
2	SWO	RO	1	SWO Trace Port Present. When set, indicates that the Serial Wire Output (SWO) trace port is present.
1	SWD	RO	1	SWD Present. When set, indicates that the Serial Wire Debugger (SWD) is present.
0	JTAG	RO	1	JTAG Present. When set, indicates that the JTAG debugger interface is present.

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11	SSI0_TX	RO	1	SSI0 TX on uDMA Ch11. When set, indicates uDMA channel 11 is available and connected to the transmit path of SSI module 0.
10	SSI0_RX	RO	1	SSI0 RX on uDMA Ch10. When set, indicates uDMA channel 10 is available and connected to the receive path of SSI module 0.
9	UART0_TX	RO	1	UART0 TX on uDMA Ch9. When set, indicates uDMA channel 9 is available and connected to the transmit path of UART module 0.
8	UART0_RX	RO	1	UART0 RX on uDMA Ch8. When set, indicates uDMA channel 8 is available and connected to the receive path of UART module 0.
7:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 23: Run Mode Clock Gating Control Register 0 (RCGC0), offset 0x100

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled (saving power). If the unit is unlocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Run Mode Clock Gating Control Register 0 (RCGC0)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:25	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
24	CAN0	R/W	0	CAN0 Clock Gating Control. This bit controls the clock gating for CAN unit 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled.
23:21	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20	PWM	R/W	0	PWM Clock Gating Control. This bit controls the clock gating for the PWM module. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.
19:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	ADC	R/W	0	ADC0 Clock Gating Control. This bit controls the clock gating for SAR ADC module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.
15:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
9:8	MAXADCSPD	R/W	0	ADC Sample Speed. This field sets the rate at which the ADC samples data. You cannot set the rate higher than the maximum rate. You can set the sample rate by setting the MAXADCSPD bit as follows: Value Description 0x2 500K samples/second 0x1 250K samples/second 0x0 125K samples/second
7:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	WDT	R/W	0	WDT Clock Gating Control. This bit controls the clock gating for the WDT module. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 24: Sleep Mode Clock Gating Control Register 0 (SCGC0), offset 0x110

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled (saving power). If the unit is unlocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

31:25	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
24	CAN0	R/W	0	CAN0 Clock Gating Control. This bit controls the clock gating for CAN unit 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled.
23:21	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20	PWM	R/W	0	PWM Clock Gating Control. This bit controls the clock gating for the PWM module. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.
19:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	ADC	R/W	0	ADC0 Clock Gating Control. This bit controls the clock gating for general SAR ADC module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.

Bit/Field	Name	Type	Reset	Description
15:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:8	MAXADCSPD	R/W	0	ADC Sample Speed. This field sets the rate at which the ADC samples data. You cannot set the rate higher than the maximum rate. You can set the sample rate by setting the MAXADCSPD bit as follows: Value Description 0x2 500K samples/second 0x1 250K samples/second 0x0 125K samples/second
7:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	WDT	R/W	0	WDT Clock Gating Control. This bit controls the clock gating for the WDT module. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 25: Deep Sleep Mode Clock Gating Control Register 0 (DCGC0), offset 0x120

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled (saving power). If the unit is unlocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC0** is the clock configuration register for running operation, **SCGC0** for Sleep operation, and **DCGC0** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Bit/Field	Name	Type	Reset	Description
31:25	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
24	CAN0	R/W	0	CAN0 Clock Gating Control. This bit controls the clock gating for CAN unit 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled.
23:21	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20	PWM	R/W	0	PWM Clock Gating Control. This bit controls the clock gating for the PWM module. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.
19:17	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	ADC	R/W	0	ADC0 Clock Gating Control. This bit controls the clock gating for general SAR ADC module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.

Bit/Field	Name	Type	Reset	Description
15:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:8	MAXADCSPD	R/W	0	ADC Sample Speed. This field sets the rate at which the ADC samples data. You cannot set the rate higher than the maximum rate. You can set the sample rate by setting the MAXADCSPD bit as follows: Value Description 0x2 500K samples/second 0x1 250K samples/second 0x0 125K samples/second
7:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	WDT	R/W	0	WDT Clock Gating Control. This bit controls the clock gating for the WDT module. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, a read or write to the unit generates a bus fault.
2:0	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 26: Run Mode Clock Gating Control Register 1 (RCGC1), offset 0x104

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unclocked and disabled (saving power). If the unit is unclocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unclocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

26	COMP2	R/W	0	Analog Comparator 2 Clock Gating. This bit controls the clock gating for analog comparator 2. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
25	COMP1	R/W	0	Analog Comparator 1 Clock Gating. This bit controls the clock gating for analog comparator 1. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
24	COMP0	R/W	0	Analog Comparator 0 Clock Gating. This bit controls the clock gating for analog comparator 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	Timer 3 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 3. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
18	TIMER2	R/W	0	Timer 2 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 2. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
17	TIMER1	R/W	0	Timer 1 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
16	TIMER0	R/W	0	Timer 0 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
15:13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control. This bit controls the clock gating for I2C module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
11:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	SSI0	R/W	0	SSI0 Clock Gating Control. This bit controls the clock gating for SSI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
3:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	UART0	R/W	0	UART0 Clock Gating Control. This bit controls the clock gating for UART module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.

Register 28: Deep Sleep Mode Clock Gating Control Register 1 (DCGC1), offset 0x124

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled (saving power). If the unit is unlocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC1** is the clock configuration register for running operation, **SCGC1** for Sleep operation, and **DCGC1** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

Deep Sleep Mode Clock Gating Control Register 1 (DCGC1)

Bit/Field	Name	Type	Reset	Description
31:27	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
26	COMP2	R/W	0	Analog Comparator 2 Clock Gating. This bit controls the clock gating for analog comparator 2. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
25	COMP1	R/W	0	Analog Comparator 1 Clock Gating. This bit controls the clock gating for analog comparator 1. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
24	COMP0	R/W	0	Analog Comparator 0 Clock Gating. This bit controls the clock gating for analog comparator 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
23:20	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
19	TIMER3	R/W	0	Timer 3 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 3. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
18	TIMER2	R/W	0	Timer 2 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 2. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
17	TIMER1	R/W	0	Timer 1 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 1. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
16	TIMER0	R/W	0	Timer 0 Clock Gating Control. This bit controls the clock gating for General-Purpose Timer module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
15:13	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
12	I2C0	R/W	0	I2C0 Clock Gating Control. This bit controls the clock gating for I2C module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
11:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	SSI0	R/W	0	SSI0 Clock Gating Control. This bit controls the clock gating for SSI module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
3:1	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	UART0	R/W	0	UART0 Clock Gating Control. This bit controls the clock gating for UART module 0. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.

Register 29: Run Mode Clock Gating Control Register 2 (RCGC2), offset 0x108

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled (saving power). If the unit is unlocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

13	UDMA	R/W	0	UDMA Clock Gating Control. This bit controls the clock gating for Port H. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
12:5	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
4	GPIOE	R/W	0	Port E Clock Gating Control. This bit controls the clock gating for Port E. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
3	GPIOD	R/W	0	Port D Clock Gating Control. This bit controls the clock gating for Port D. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
2	GPIOC	R/W	0	Port C Clock Gating Control. This bit controls the clock gating for Port C. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.

Bit/Field	Name	Type	Reset	Description
1	GPIOB	R/W	0	Port B Clock Gating Control. This bit controls the clock gating for Port B. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.
0	GPIOA	R/W	0	Port A Clock Gating Control. This bit controls the clock gating for Port A. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled. If the unit is unlocked, reads or writes to the unit will generate a bus fault.

Register 30: Sleep Mode Clock Gating Control Register 2 (SCGC2), offset 0x118

This register controls the clock gating logic. Each bit controls a clock enable for a given interface, function, or unit. If set, the unit receives a clock and functions. Otherwise, the unit is unlocked and disabled (saving power). If the unit is unlocked, reads or writes to the unit will generate a bus fault. The reset state of these bits is 0 (unlocked) unless otherwise noted, so that all functional units are disabled. It is the responsibility of software to enable the ports necessary for the application. Note that these registers may contain more bits than there are interfaces, functions, or units to control. This is to assure reasonable code compatibility with other family and future parts. **RCGC2** is the clock configuration register for running operation, **SCGC2** for Sleep operation, and **DCGC2** for Deep-Sleep operation. Setting the **ACG** bit in the **Run-Mode Clock Configuration (RCC)** register specifies that the system uses sleep modes.

7 Internal Memory

The LM3S2671 microcontroller comes with 32 KB of bit-banded SRAM and 128 KB of flash memory. The flash controller provides a user-friendly interface, making flash programming a simple task. Flash protection can be applied to the flash memory on a 2-KB block basis.

7.1 Block Diagram

Figure 7-1 on page 127 illustrates the Flash functions. The dashed boxes in the figure indicate registers residing in the System Control module rather than the Flash Control module.

Figure 7-1. Flash Block Diagram

7.2 Functional Description

This section describes the functionality of the SRAM, ROM, and Flash memories.

7.2.1 SRAM Memory

Note: The SRAM memory is implemented using two 32-bit wide SRAM banks (separate SRAM arrays). The banks are partitioned so that one bank contains all even words (the even bank) and the other contains all odd words (the odd bank). A write access that is followed immediately by a read access to the same bank will incur a stall of a single clock cycle. However, a write to one bank followed by a read of the other bank can occur in successive clock cycles without incurring any delay.

The internal SRAM of the Stellaris® devices is located at address 0x2000.0000 of the device memory map. To reduce the number of time consuming read-modify-write (RMW) operations, ARM has introduced *bit-banding* technology in the Cortex-M3 processor. With a bit-band-enabled processor, certain regions in the memory map (SRAM and peripheral space) can use address aliases to access individual bits in a single, atomic operation.

The bit-band alias is calculated by using the formula:

$$\text{bit-band alias} = \text{bit-band base} + (\text{byte offset} * 32) + (\text{bit number} * 4)$$

For example, if bit 3 at address 0x2000.1000 is to be modified, the bit-band alias is calculated as:

$$0x2200.0000 + (0x1000 * 32) + (3 * 4) = 0x2202.000C$$

With the alias address calculated, an instruction performing a read/write to address 0x2202.000C allows direct access to only bit 3 of the byte at address 0x2000.1000.

For details about bit-banding, please refer to Chapter 4, “Memory Map” in the *ARM® Cortex™-M3 Technical Reference Manual*.

7.2.2 ROM Memory

The 16 KB of internal ROM of the Stellaris® device is located at address 0x0100.0000 of the device memory map and contains the following components:

- A copy of the Serial Flash Loader and vector table
- A copy of the peripheral driver library (DriverLib) release for product-specific peripherals and interfaces
- Some pre-loaded code provided for manufacturing tests

7.2.3 Flash Memory

The flash is organized as a set of 1-KB blocks that can be individually erased. Erasing a block causes the entire contents of the block to be reset to all 1s. An individual 32-bit word can be programmed to change bits that are currently 1 to a 0. These blocks are paired into a set of 2-KB blocks that can be individually protected. The protection allows blocks to be marked as read-only or execute-only, providing different levels of code protection. Read-only blocks cannot be erased or programmed, protecting the contents of those blocks from being modified. Execute-only blocks cannot be erased or programmed, and can only be read by the controller instruction fetch mechanism, protecting the contents of those blocks from being read by either the controller or by a debugger.

7.2.3.1 Flash Memory Timing

The timing for the flash is automatically handled by the flash controller. However, in order to do so, it must know the clock rate of the system in order to time its internal signals properly. The number of clock cycles per microsecond must be provided to the flash controller for it to accomplish this timing. It is software's responsibility to keep the flash controller updated with this information via the **Usec Reload (USECRL)** register.

On reset, the **USECRL** register is loaded with a value that configures the flash timing so that it works with the maximum clock rate of the part. If software changes the system operating frequency, the new operating frequency minus 1 (in MHz) must be loaded into **USECRL** before any flash modifications are attempted. For example, if the device is operating at a speed of 20 MHz, a value of 0x13 (20-1) must be written to the **USECRL** register.

7.2.3.2 Flash Memory Protection

The user is provided two forms of flash protection per 2-KB flash blocks in two pairs of 32-bit wide registers. The protection policy for each form is controlled by individual bits (per policy per block) in the **FMPPEn** and **FMPREn** registers.

- **Flash Memory Protection Program Enable (FMPPEn)**: If set, the block may be programmed (written) or erased. If cleared, the block may not be changed.
- **Flash Memory Protection Read Enable (FMPREn)**: If set, the block may be executed or read by software or debuggers. If cleared, the block may only be executed and contents of the memory block are prohibited from being accessed as data.

The policies may be combined as shown in Table 7-1 on page 129.

Table 7-1. Flash Protection Policy Combinations

FMPPEn	FMPREn	Protection
0	0	Execute-only protection. The block may only be executed and may not be written or erased. This mode is used to protect code.
1	0	The block may be written, erased or executed, but not read. This combination is unlikely to be used.
0	1	Read-only protection. The block may be read or executed but may not be written or erased. This mode is used to lock the block from further modification while allowing any read or execute access.
1	1	No protection. The block may be written, erased, executed or read.

An access that attempts to program or erase a PE-protected block is prohibited. A controller interrupt may be optionally generated (by setting the **AMASK** bit in the **FIM** register) to alert software developers of poorly behaving software during the development and debug phases.

An access that attempts to read an RE-protected block is prohibited. Such accesses return data filled with all 0s. A controller interrupt may be optionally generated to alert software developers of poorly behaving software during the development and debug phases.

The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This implements a policy of open access and programmability. The register bits may be changed by writing the specific register bit. The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. Details on programming these bits are discussed in “Nonvolatile Register Programming” on page 130.

7.3 Flash Memory Initialization and Configuration

7.3.1 Flash Programming

The Stellaris[®] devices provide a user-friendly interface for flash programming. All erase/program operations are handled via three registers: **FMA**, **FMD**, and **FMC**.

7.3.1.1 To program a 32-bit word

1. Write source data to the **FMD** register.
2. Write the target address to the **FMA** register.
3. Write the flash write key and the **WRITE** bit (a value of 0xA442.0001) to the **FMC** register.

4. Poll the **FMC** register until the `WRITE` bit is cleared.

7.3.1.2 To perform an erase of a 1-KB page

1. Write the page address to the **FMA** register.
2. Write the flash write key and the `ERASE` bit (a value of `0xA442.0002`) to the **FMC** register.
3. Poll the **FMC** register until the `ERASE` bit is cleared.

7.3.1.3 To perform a mass erase of the flash

1. Write the flash write key and the `MERASE` bit (a value of `0xA442.0004`) to the **FMC** register.
2. Poll the **FMC** register until the `MERASE` bit is cleared.

7.3.2 Nonvolatile Register Programming

This section discusses how to update registers that are resident within the flash memory itself. These registers exist in a separate space from the main flash array and are not affected by an `ERASE` or `MASS ERASE` operation. These nonvolatile registers are updated by using the `COMT` bit in the **FMC** register to activate a write operation. For the **USER_DBG** register, the data to be written must be loaded into the **FMD** register before it is "committed". All other registers are R/W and can have their operation tried before committing them to nonvolatile memory.

Important: These registers can only have bits changed from 1 to 0 by user programming, but can be restored to their factory default values by performing the sequence described in the section called "Recovering a "Locked" Device" on page 56. The mass erase of the main flash array caused by the sequence is performed prior to restoring these registers.

In addition, the **USER_REG0**, **USER_REG1**, and **USER_DBG** use bit 31 (NW) of their respective registers to indicate that they are available for user write. These three registers can only be written once whereas the flash protection registers may be written multiple times. Table 7-2 on page 130 provides the FMA address required for commitment of each of the registers and the source of the data to be written when the `COMT` bit of the **FMC** register is written with a value of `0xA442.0008`. After writing the `COMT` bit, the user may poll the **FMC** register to wait for the commit operation to complete.

Table 7-2. Flash Resident Registers^a

Register to be Committed	FMA Value	Data Source
FMPRE0	0x0000.0000	FMPRE0
FMPRE1	0x0000.0002	FMPRE1
FMPRE2	0x0000.0004	FMPRE2
FMPRE3	0x0000.0008	FMPRE3
FMPPE0	0x0000.0001	FMPPE0
FMPPE1	0x0000.0003	FMPPE1
FMPPE2	0x0000.0005	FMPPE2
FMPPE3	0x0000.0007	FMPPE3
USER_REG0	0x8000.0000	USER_REG0
USER_REG1	0x8000.0001	USER_REG1

Register to be Committed	FMA Value	Data Source
USER_DBG	0x7510.0000	FMD

a. Which FMPREn and FMPPEn registers are available depend on the flash size of your particular Stellaris® device.

7.4 Register Map

Table 7-3 on page 131 lists the ROM Controller registers and the Flash memory and control registers. The offset listed is a hexadecimal increment to the register's address. The ROM Controller registers are relative to the System Control base address of 0x400F.E000. The **FMA**, **FMD**, **FMC**, **FCRIS**, **FCIM**, and **FCMISC** registers are relative to the Flash control base address of 0x400F.D000. The **FMPREn**, **FMPPEn**, **USECRL**, **USER_DBG**, and **USER_REGn** registers are relative to the System Control base address of 0x400F.E000.

Table 7-3. Flash Register Map

Offset	Name	Type	Reset	Description	See page
ROM Registers (System Control Offset)

7.5 ROM Register Descriptions (System Control Offset)

This section lists and describes the ROM Controller registers, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

Register 1: ROM Control (RMCTL), offset 0x0F0

This register provides control of the ROM controller state.

ROM Control (RMCTL)

Base 0x400F.E000

Offset 0x0F0

Type R/W1C, reset -

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	-

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	BA	R/W1C	-	Boot Alias

- The device has ROM.
- The first two words of the Flash memory contain 0xFFFF.FFFF.

This bit is cleared by writing a 1 to this bit position.

When the `BA` bit is set, the boot alias is in effect and the ROM appears at address 0x0. When the `BA` bit is clear, the Flash appears at address 0x0.

7.6 Flash Register Descriptions (Flash Control Offset)

This section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the Flash control base address of 0x400F.D000.

Register 2: Flash Memory Address (FMA), offset 0x000

During a write operation, this register contains a 4-byte-aligned address and specifies where the data is written. During erase operations, this register contains a 1 KB-aligned address and specifies which page is erased. Note that the alignment requirements must be met by software or the results of the operation are unpredictable.

Flash Memory Address (FMA)

Base 0x400F.D000
 Offset 0x000
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16:0	OFFSET	R/W	0x0	Address Offset Address offset in flash where operation is performed, except for nonvolatile registers (see "Nonvolatile Register Programming" on page 130 for details on values for this field).

Register 3: Flash Memory Data (FMD), offset 0x004

This register contains the data to be written during the programming cycle or read during the read cycle. Note that the contents of this register are undefined for a read access of an execute-only block. This register is not used during the erase cycles.

Flash Memory Data (FMD)

Base 0x400F.D000

Offset 0x004

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:0	DATA	R/W	0x0	Data Value Data value for write operation.

Register 4: Flash Memory Control (FMC), offset 0x008

When this register is written, the flash controller initiates the appropriate access cycle for the location specified by the **Flash Memory Address (FMA)** register (see page 134). If the access is a write access, the data contained in the **Flash Memory Data (FMD)** register (see page 135) is written.

This is the final register written and initiates the memory operation. There are four control bits in the lower byte of this register that, when set, initiate the memory operation. The most used of these register bits are the `ERASE` and `WRITE` bits.

It is a programming error to write multiple control bits and the results of such an operation are unpredictable.

Flash Memory Control (FMC)

Base 0x400F.D000

Offset 0x008

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WRKEY															
Type	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO	WO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	WRKEY	WO	0x0	Flash Write Key This field contains a write key, which is used to minimize the incidence of accidental flash writes. The value 0xA442 must be written into this field for a write to occur. Writes to the FMC register without this <code>WRKEY</code> value are ignored. A read of this field returns the value 0.
15:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	COMT	R/W	0	Commit Register Value Commit (write) of register value to nonvolatile storage. A write of 0 has no effect on the state of this bit. If read, the state of the previous commit access is provided. If the previous commit access is complete, a 0 is returned; otherwise, if the commit access is not complete, a 1 is returned. This can take up to 50 μ s.
2	MERASE	R/W	0	Mass Erase Flash Memory If this bit is set, the flash main memory of the device is all erased. A write of 0 has no effect on the state of this bit. If read, the state of the previous mass erase access is provided. If the previous mass erase access is complete, a 0 is returned; otherwise, if the previous mass erase access is not complete, a 1 is returned. This can take up to 250 ms.

Bit/Field	Name	Type	Reset	Description
1	ERASE	R/W	0	<p>Erase a Page of Flash Memory</p> <p>If this bit is set, the page of flash main memory as specified by the contents of FMA is erased. A write of 0 has no effect on the state of this bit.</p> <p>If read, the state of the previous erase access is provided. If the previous erase access is complete, a 0 is returned; otherwise, if the previous erase access is not complete, a 1 is returned.</p> <p>This can take up to 25 ms.</p>
0	WRITE	R/W	0	<p>Write a Word into Flash Memory</p> <p>If this bit is set, the data stored in FMD is written into the location as specified by the contents of FMA. A write of 0 has no effect on the state of this bit.</p> <p>If read, the state of the previous write update is provided. If the previous write access is complete, a 0 is returned; otherwise, if the write access is not complete, a 1 is returned.</p> <p>This can take up to 50 μs.</p>

Register 5: Flash Controller Raw Interrupt Status (FCRIS), offset 0x00C

This register indicates that the flash controller has an interrupt condition. An interrupt is only signaled if the corresponding **FCIM** register bit is set.

Flash Controller Raw Interrupt Status (FCRIS)

Base 0x400F.D000

Offset 0x00C

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PMISC	R/W1C	0	Programming Masked Interrupt Status and Clear This bit indicates whether an interrupt was signaled because a programming cycle completed and was not masked. This bit is cleared by writing a 1. The <code>PRIS</code> bit in the <code>FCRIS</code> register (see page 138) is also cleared when the <code>PMISC</code> bit is cleared.
0	AMISC	R/W1C	0	Access Masked Interrupt Status and Clear This bit indicates whether an interrupt was signaled because an improper access was attempted and was not masked. This bit is cleared by writing a 1. The <code>ARIS</code> bit in the <code>FCRIS</code> register is also cleared when the <code>AMISC</code> bit is cleared.

7.7 Flash Register Descriptions (System Control Offset)

The remainder of this section lists and describes the Flash Memory registers, in numerical order by address offset. Registers in this section are relative to the System Control base address of 0x400F.E000.

Register 8: USec Reload (USECRL), offset 0x140

Note: Offset is relative to System Control base address of 0x400F.E000

This register is provided as a means of creating a 1- μ s tick divider reload value for the flash controller. The internal flash has specific minimum and maximum requirements on the length of time the high voltage write pulse can be applied. It is required that this register contain the operating frequency (in MHz -1) whenever the flash is being erased or programmed. The user is required to change this value if the clocking conditions are changed for a flash erase/program operation.

USec Reload (USECRL)

Base 0x400F.E000

Offset 0x140

Type R/W, reset 0x31

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Reset	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	1

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	USEC	R/W	0x31	Microsecond Reload Value MHz -1 of the controller clock when the flash is being erased or programmed. If the maximum system frequency is being used, USEC should be set to 0x31 (50 MHz) whenever the flash is being erased or programmed.

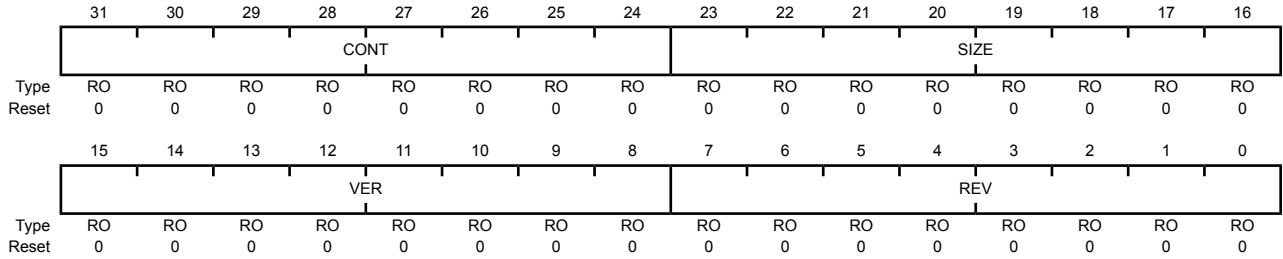

Register 9: ROM Version Register (RMVER), offset 0x0F4

Note: Offset is relative to System Control base address of 0x400FE000.

A 32-bit read-only register containing the ROM content version information.

ROM Version Register (RMVER)

Base 0x400F.E000
 Offset 0x0F4
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:24	CONT	RO	0x0	ROM Contents This field specifies the contents of the ROM. Value Description 0x0 Stellaris Boot Loader & DriverLib
23:16	SIZE	RO	0x0	ROM Size This field encodes the size of the ROM. Value Description 0x0 11 KB
15:8	VER	RO	0x0	ROM Version
7:0	REV	RO	0x0	ROM Revision

Register 10: Flash Memory Protection Read Enable 0 (FMPRE0), offset 0x130 and 0x200

Note: This register is aliased for backwards compatibility.

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 0 (FMPRE0)

Base 0x400F.E000

Offset 0x130 and 0x200

Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0xFFFFFFFF	Flash Read Enable. Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
	Value	Description		
	0xFFFFFFFF	Enables 128 KB of flash.		

Register 11: Flash Memory Protection Program Enable 0 (FMPPE0), offset 0x134 and 0x400

Note: This register is aliased for backwards compatability.

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPREn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREn** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Program Enable 0 (FMPPE0)

Base 0x400F.E000
 Offset 0x134 and 0x400
 Type R/W, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	PROG_ENABLE	R/W	0xFFFFFFFF	Flash Programming Enable Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
	Value	Description		
	0xFFFFFFFF	Enables 128 KB of flash.		

Register 12: User Debug (USER_DBG), offset 0x1D0

Note: Offset is relative to System Control base address of 0x400FE000.

This register provides a write-once mechanism to disable external debugger access to the device in addition to 27 additional bits of user-defined data. The `DBG0` bit (bit 0) is set to 0 from the factory and the `DBG1` bit (bit 1) is set to 1, which enables external debuggers. Changing the `DBG1` bit to 0 disables any external debugger access to the device permanently, starting with the next power-up cycle of the device. The `NOTWRITTEN` bit (bit 31) indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once.

User Debug (USER_DBG)

Base 0x400F.E000

Offset 0x1D0

Type R/W, reset 0xFFFF.FFFE

1	DBG1	R/W	1	Debug Control 1. The <code>DBG1</code> bit must be 1 and <code>DBG0</code> must be 0 for debug to be available.
0	DBG0	R/W	0	Debug Control 0. The <code>DBG1</code> bit must be 1 and <code>DBG0</code> must be 0 for debug to be available.

Register 13: User Register 0 (USER_REG0), offset 0x1E0

Note: Offset is relative to System Control base address of 0x400FE000.

This register provides 31 bits of user-defined data that is non-volatile and can only be written once. Bit 31 indicates that the register is available to be written and is controlled through hardware to ensure that the register is only written once. The write-once characteristics of this register are useful for keeping static information like communication addresses that need to be unique per part and would otherwise require an external EEPROM or other non-volatile device.

Register 17: Flash Memory Protection Read Enable 1 (FMPRE1), offset 0x204

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 1 (FMPRE1)

Base 0x400F.E000
 Offset 0x204
 Type R/W, reset 0xFFFFFFFF

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0xFFFFFFFF	Flash Read Enable. Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value Description
				0xFFFFFFFF Enables 128 KB of flash.

Register 18: Flash Memory Protection Read Enable 2 (FMPRE2), offset 0x208

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 2 (FMPRE2)

Base 0x400F.E000

Offset 0x208

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0x00000000	Flash Read Enable. Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value Description
				0x00000000 Enables 128 KB of flash.

Register 19: Flash Memory Protection Read Enable 3 (FMPRE3), offset 0x20C

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the read-only protection bits for each 2-KB flash block (**FMPPEn** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPREN** and **FMPPEn** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Flash Memory Protection Read Enable 3 (FMPRE3)

Base 0x400F.E000
 Offset 0x20C
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	READ_ENABLE	R/W	0x00000000	Flash Read Enable. Enables 2-KB flash blocks to be executed or read. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value Description
				0x00000000 Enables 128 KB of flash.

Register 20: Flash Memory Protection Program Enable 1 (FMPPE1), offset 0x404

Note: Offset is relative to System Control base address of 0x400FE000.

This register stores the execute-only protection bits for each 2-KB flash block (**FMPPE_n** stores the execute-only bits). This register is loaded during the power-on reset sequence. The factory settings for the **FMPPE_n** and **FMPPE_n** registers are a value of 1 for all implemented banks. This achieves a policy of open access and programmability. The register bits may be changed by writing the specific register bit. However, this register is R/W0; the user can only change the protection bit from a 1 to a 0 (and may NOT change a 0 to a 1). The changes are not permanent until the register is committed (saved), at which point the bit change is permanent. If a bit is changed from a 1 to a 0 and not committed, it may be restored by executing a power-on reset sequence. For additional information, see the "Flash Memory Protection" section.

Bit/Field	Name	Type	Reset	Description
31:0	PROG_ENABLE	R/W	0x00000000	Flash Programming Enable. Configures 2-KB flash blocks to be execute only. The policies may be combined as shown in the table "Flash Protection Policy Combinations".
				Value Description
			0x00000000	Enables 128 KB of flash.

8 Micro Direct Memory Access (μ DMA)

The LM3S2671 microcontroller includes a Direct Memory Access (DMA) controller, known as micro-DMA (μ DMA). The μ DMA controller provides a way to offload data transfer tasks from the Cortex-M3 processor, allowing for more efficient use of the processor and the expanded available bus bandwidth. The μ DMA controller can perform transfers between memory and peripherals. It has dedicated channels for each supported peripheral and can be programmed to automatically perform transfers between peripherals and memory as the peripheral is ready to transfer more data. The μ DMA controller also supports sophisticated transfer modes such as ping-pong and scatter-gather, which allows the processor to set up a list of transfer tasks for the controller.

The μ DMA controller has the following features:

- ARM PrimeCell® 32-channel configurable μ DMA controller
- Support for multiple transfer modes:
 - Basic, for simple transfer scenarios
 - Ping-pong, for continuous data flow to/from peripherals
 - Scatter-gather, from a programmable list of arbitrary transfers initiated from a single request
- Dedicated channels for supported peripherals
- One channel each for receive and transmit path for bidirectional peripherals
- Dedicated channel for software-initiated transfers
- Independently configured and operated channels
- Per-channel configurable bus arbitration scheme
- Two levels of priority
- Design optimizations for improved bus access performance between μ DMA controller and the processor core:
 - μ DMA controller access is subordinate to core access
 - RAM striping
 - Peripheral bus segmentation
- Data sizes of 8, 16, and 32 bits
- Source and destination address increment size of byte, half-word, word, or no increment
- Maskable device requests
- Optional software initiated requests for any channel
- Interrupt on transfer completion, with a separate interrupt per channel

8.1 Block Diagram

Figure 8-1. μ DMA Block Diagram

8.2 Functional Description

The μ DMA controller is a flexible and highly configurable DMA controller designed to work efficiently with the microcontroller's Cortex-M3 processor core. It supports multiple data sizes and address increment schemes, multiple levels of priority among DMA channels, and several transfer modes to allow for sophisticated programmed data transfers. The DMA controller's usage of the bus is always subordinate to the processor core, and so it will never hold up a bus transaction by the processor. Because the μ DMA controller is only using otherwise-idle bus cycles, the data transfer bandwidth it provides is essentially free, with no impact on the rest of the system. The bus architecture has been optimized to greatly reduce contention between the processor core and the μ DMA controller, thus improving performance. The optimizations include RAM striping and peripheral bus segmentation, which in many cases allows both the processor core and the μ DMA controller to access the bus and perform simultaneous data transfers.

Each peripheral function that is supported has a dedicated channel on the μ DMA controller that can be configured independently.

The μ DMA controller makes use of a unique configuration method by using channel control structures that are maintained in system memory by the processor. While simple transfer modes are supported, it is also possible to build up sophisticated "task" lists in memory that allow the controller to perform arbitrary-sized transfers to and from arbitrary locations as part of a single transfer request. The controller also supports the use of ping-pong buffering to accommodate constant streaming of data to or from a peripheral.

Each channel also has a configurable arbitration size. The arbitration size is the number of items that will be transferred in a burst before the controller re-arbitrates for channel priority. Using the arbitration size, it is possible to control exactly how many items are transferred to or from a peripheral each time it makes a DMA service request.

8.2.1 Channel Assignments

μ DMA channels 0-31 are assigned to peripherals according to the following table.

Note: Channels that are not listed in the table may be assigned to peripherals in the future. However, they are currently available for software use.

Table 8-1. DMA Channel Assignments

DMA Channel	Peripheral Assigned
8	UART0 Receive
9	UART0 Transmit
10	SSI0 Receive
11	SSI0 Transmit
30	Dedicated for software use

8.2.2 Priority

The μ DMA controller assigns priority to each channel based on the channel number and the priority level bit for the channel. Channel number 0 has the highest priority and as the channel number increases, the priority of a channel decreases. Each channel has a priority level bit to provide two levels of priority: default priority and high priority. If the priority level bit is set, then that channel has higher priority than all other channels at default priority. If multiple channels are set for high priority, then the channel number is used to determine relative priority among all the high priority channels.

The priority bit for a channel can be set using the **DMA Channel Priority Set (DMAPRIOSET)** register, and cleared with the **DMA Channel Priority Clear (DMAPRIOCLR)** register.

8.2.3 Arbitration Size

When a μ DMA channel requests a transfer, the μ DMA controller arbitrates between all the channels making a request and services the DMA channel with the highest priority. Once a transfer begins, it continues for a selectable number of transfers before re-arbitrating among the requesting channels again. The arbitration size can be configured for each channel, ranging from 1 to 1024 item transfers. After the μ DMA controller transfers the number of items specified by the arbitration size, it then checks among all the channels making a request and services the channel with the highest priority.

If a lower priority DMA channel uses a large arbitration size, the latency for higher priority channels will be increased because the μ DMA controller will complete the lower priority burst before checking for higher priority requests. Therefore, lower priority channels should not use a large arbitration size for best response on high priority channels.

The arbitration size can also be thought of as a burst size. It is the maximum number of items that will be transferred at any one time in a burst. Here, the term arbitration refers to determination of DMA channel priority, not arbitration for the bus. When the μ DMA controller arbitrates for the bus, the processor always takes priority. Furthermore, the μ DMA controller will be held off whenever the processor needs to perform a bus transaction on the same bus, even in the middle of a burst transfer.

8.2.4 Request Types

The μ DMA controller responds to two types of requests from a peripheral: single or burst. Each peripheral may support either or both types of requests. A single request means that the peripheral is ready to transfer one item, while a burst request means that the peripheral is ready to transfer multiple items.

The μ DMA controller responds differently depending on whether the peripheral is making a single request or a burst request. If both are asserted and the μ DMA channel has been set up for a burst transfer, then the burst request takes precedence. See Table 8-2 on page 159, which shows how each peripheral supports the two request types.

Table 8-2. Request Type Support

Peripheral	Single Request Signal	Burst Request Signal
UART TX	TX FIFO Not Full	TX FIFO Level (configurable)
UART RX	RX FIFO Not Empty	RX FIFO Level (configurable)
SSI TX	TX FIFO Not Full	TX FIFO Level (fixed at 4)
SSI RX	RX FIFO Not Empty	RX FIFO Level (fixed at 4)

8.2.4.1 Single Request

When a single request is detected, and not a burst request, the μ DMA controller will transfer one item, and then stop and wait for another request.

8.2.4.2 Burst Request

When a burst request is detected, the μ DMA controller will transfer the number of items that is the lesser of the arbitration size or the number of items remaining in the transfer. Therefore, the arbitration size should be the same as the number of data items that the peripheral can accommodate when making a burst request. For example, the UART will generate a burst request based on the FIFO trigger level. In this case, the arbitration size should be set to the amount of data that the FIFO can transfer when the trigger level is reached.

It may be desirable to use only burst transfers and not allow single transfers. For example, perhaps the nature of the data is such that it only makes sense when transferred together as a single unit rather than one piece at a time. The single request can be disabled by using the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register. By setting the bit for a channel in this register, the μ DMA controller will only respond to burst requests for that channel.

8.2.5 Channel Configuration

The μ DMA controller uses an area of system memory to store a set of channel control structures in a table. The control table may have one or two entries for each DMA channel. Each entry in the table structure contains source and destination pointers, transfer size, and transfer mode. The control table can be located anywhere in system memory, but it must be contiguous and aligned on a 1024-byte boundary.

Table 8-3 on page 160 shows the layout in memory of the channel control table. Each channel may have one or two control structures in the control table: a primary control structure and an optional alternate control structure. The table is organized so that all of the primary entries are in the first half of the table and all the alternate structures are in the second half of the table. The primary entry is used for simple transfer modes where transfers can be reconfigured and restarted after each transfer is complete. In this case, the alternate control structures are not used and therefore only the first half of the table needs to be allocated in memory. The second half of the control table is not needed and that memory can be used for something else. If a more complex transfer mode is used such as ping-pong or scatter-gather, then the alternate control structure is also used and memory space should be allocated for the entire table.

Any unused memory in the control table may be used by the application. This includes the control structures for any channels that are unused by the application as well as the unused control word for each channel.

Table 8-3. Control Structure Memory Map

Offset	Channel
0x0	0, Primary
0x10	1, Primary
...	...
0x1F0	31, Primary
0x200	0, Alternate
0x210	1, Alternate
...	...
0x3F0	31, Alternate

Table 8-4 on page 160 shows an individual control structure entry in the control table. Each entry has a source and destination *end* pointer. These pointers point to the ending address of the transfer and are inclusive. If the source or destination is non-incrementing (as for a peripheral register), then the pointer should point to the transfer address.

Table 8-4. Channel Control Structure

Offset	Description
0x000	Source End Pointer
0x004	Destination End Pointer
0x008	Control Word
0x00C	Unused

The remaining part of the control structure is the control word. The control word contains the following fields:

- Source and destination data sizes
- Source and destination address increment size
- Number of transfers before bus arbitration
- Total number of items to transfer
- Useburst flag
- Transfer mode

The control word and each field are described in detail in “ μ DMA Channel Control Structure” on page 177. The μ DMA controller updates the transfer size and transfer mode fields as the transfer is performed. At the end of a transfer, the transfer size will indicate 0, and the transfer mode will indicate "stopped". Since the control word is modified by the μ DMA controller, it must be reconfigured before each new transfer. The source and destination end pointers are not modified so they can be left unchanged if the source or destination addresses remain the same.

Prior to starting a transfer, a μ DMA channel must be enabled by setting the appropriate bit in the **DMA Channel Enable Set ((DMAENASET)** register. A channel can be disabled by setting the channel bit in the **DMA Channel Enable Clear (DMAENACLR)** register. At the end of a complete DMA transfer, the controller will automatically disable the channel.

8.2.6 Transfer Modes

The μ DMA controller supports several transfer modes. Two of the modes support simple one-time transfers. There are several complex modes that are meant to support a continuous flow of data.

8.2.6.1 Stop Mode

While Stop is not actually a transfer mode, it is a valid value for the mode field of the control word. When the mode field has this value, the μ DMA controller will not perform a transfer and will disable the channel if it is enabled. At the end of a transfer, the μ DMA controller will update the control word to set the mode to Stop.

8.2.6.2 Basic Mode

In Basic mode, the μ DMA controller will perform transfers as long as there are more items to transfer and a transfer request is present. This mode is used with peripherals that assert a DMA request signal whenever the peripheral is ready for a data transfer. Basic mode should not be used in any situation where the request is momentary but the entire transfer should be completed. For example, for a software initiated transfer, the request is momentary, and if Basic mode is used then only one item will be transferred on a software request.

When all of the items have been transferred using Basic mode, the μ DMA controller will set the mode for that channel to Stop.

8.2.6.3 Auto Mode

Auto mode is similar to Basic mode, except that once a transfer request is received the transfer will run to completion, even if the DMA request is removed. This mode is suitable for software-triggered transfers. Generally, you would not use Auto mode with a peripheral.

When all the items have been transferred using Auto mode, the μ DMA controller will set the mode for that channel to Stop.

8.2.6.4 Ping-Pong

Ping-Pong mode is used to support a continuous data flow to or from a peripheral. To use Ping-Pong mode, both the primary and alternate data structures are used. Both are set up by the processor for data transfer between memory and a peripheral. Then the transfer is started using the primary control structure. When the transfer using the primary control structure is complete, the μ DMA controller will then read the alternate control structure for that channel to continue the transfer. Each time this happens, an interrupt is generated and the processor can reload the control structure for the just-completed transfer. Data flow can continue indefinitely this way, using the primary and alternate control structures to switch back and forth between buffers as the data flows to or from the peripheral.

Refer to Figure 8-2 on page 162 for an example showing operation in Ping-Pong mode.

Figure 8-2. Example of Ping-Pong DMA Transaction

8.2.6.5 Memory Scatter-Gather

Memory Scatter-Gather mode is a complex mode used when data needs to be transferred to or from varied locations in memory instead of a set of contiguous locations in a memory buffer. For example, a gather DMA operation could be used to selectively read the payload of several stored packets of a communication protocol, and store them together in sequence in a memory buffer.

In Memory Scatter-Gather mode, the primary control structure is used to program the alternate control structure from a table in memory. The table is set up by the processor software and contains a list of control structures, each containing the source and destination end pointers, and the control word for a specific transfer. The mode of each control word must be set to Scatter-Gather mode. Each entry in the table is copied in turn to the alternate structure where it is then executed. The μ DMA controller alternates between using the primary control structure to copy the next transfer instruction from the list, and then executing the new transfer instruction. The end of the list is marked by setting the control word for the last entry to use Basic transfer mode. Once the last transfer is performed using Basic mode, the μ DMA controller will stop. A completion interrupt will only be generated after the last transfer. It is possible to loop the list by having the last entry copy the primary control structure to point back to the beginning of the list (or to a new list). It is also possible to trigger a set of other channels to perform a transfer, either directly by programming a write to the software trigger for another channel, or indirectly by causing a peripheral action that will result in a μ DMA request.

By programming the μ DMA controller using this method, a set of arbitrary transfers can be performed based on a single DMA request.

Refer to Figure 8-3 on page 164 and Figure 8-4 on page 165, which show an example of operation in Memory Scatter-Gather mode. This example shows a *gather* operation, where data in three separate buffers in memory will be copied together into one buffer. Figure 8-3 on page 164 shows how the application sets up a μ DMA *task list* in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that will be used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-4 on page 165 shows the sequence as the μ DMA controller performs the three sets of copy operations. First, using the primary control structure, the μ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the destination buffer. Next, the μ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

Figure 8-3. Memory Scatter-Gather, Setup and Configuration

NOTES:

1. Application has a need to copy data items from three separate location in memory into one combined buffer.
2. Application sets up μ DMA "task list" in memory, which contains the pointers and control configuration for three μ DMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it will be executed by the μ DMA controller.

Figure 8-4. Memory Scatter-Gather, μ DMA Copy Sequence

Using the channel's primary control structure, the μ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer A to the destination buffer.

Using the channel's primary control structure, the μ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer B to the destination buffer.

Using the channel's primary control structure, the μ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer C to the destination buffer.

8.2.6.6 Peripheral Scatter-Gather

Peripheral Scatter-Gather mode is very similar to Memory Scatter-Gather, except that the transfers are controlled by a peripheral making a DMA request. Upon detecting a DMA request from the peripheral, the μ DMA controller will use the primary control structure to copy one entry from the list to the alternate control structure, and then perform the transfer. At the end of this transfer, the next transfer will only be started if the peripheral again asserts a DMA request. The μ DMA controller will continue to perform transfers from the list only when the peripheral is making a request, until the last transfer is complete. A completion interrupt will only be generated after the last transfer.

By programming the μ DMA controller using this method, data can be transferred to or from a peripheral from a set of arbitrary locations whenever the peripheral is ready to transfer data.

Refer to Figure 8-5 on page 167 and Figure 8-6 on page 168, which show an example of operation in Peripheral Scatter-Gather mode. This example shows a gather operation, where data from three separate buffers in memory will be copied to a single peripheral data register. Figure 8-5 on page 167 shows how the application sets up a μ DMA task list in memory that is used by the controller to perform three sets of copy operations from different locations in memory. The primary control structure for the channel that will be used for the operation is configured to copy from the task list to the alternate control structure.

Figure 8-6 on page 168 shows the sequence as the μ DMA controller performs the three sets of copy operations. First, using the primary control structure, the μ DMA controller loads the alternate control structure with task A. It then performs the copy operation specified by task A, copying the data from the source buffer A to the peripheral data register. Next, the μ DMA controller again uses the primary control structure to load task B into the alternate control structure, and then performs the B operation with the alternate control structure. The process is repeated for task C.

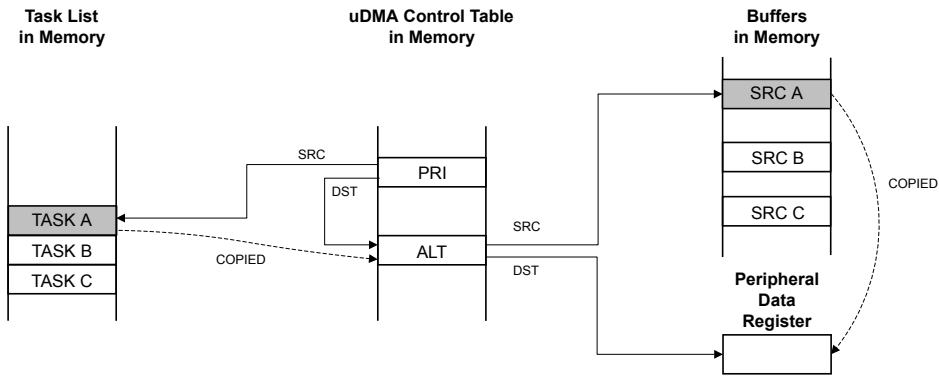

Figure 8-5. Peripheral Scatter-Gather, Setup and Configuration

NOTES:

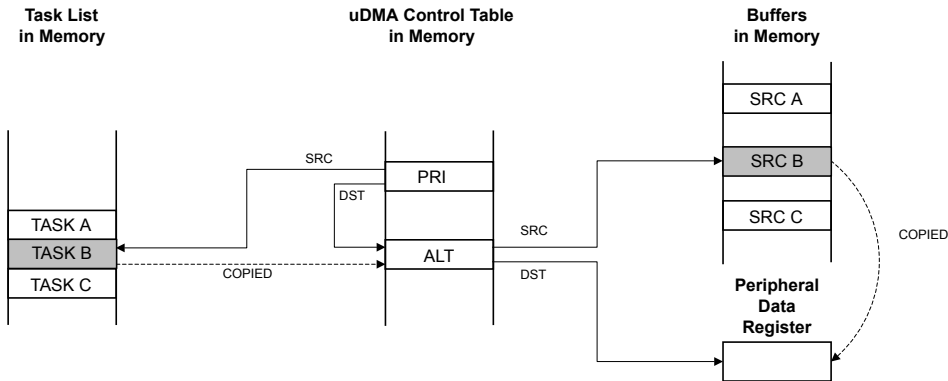

1. Application has a need to copy data items from three separate location in memory into a peripheral data register.
2. Application sets up uDMA "task list" in memory, which contains the pointers and control configuration for three uDMA copy "tasks."
3. Application sets up the channel primary control structure to copy each task configuration, one at a time, to the alternate control structure, where it will be executed by the uDMA controller.

Figure 8-6. Peripheral Scatter-Gather, μ DMA Copy Sequence

Using the channel's primary control structure, the μ DMA controller copies task A configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer A to the peripheral data register.

Using the channel's primary control structure, the μ DMA controller copies task B configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer B to the peripheral data register.

Using the channel's primary control structure, the μ DMA controller copies task C configuration to the channel's alternate control structure.

Then, using the channel's alternate control structure, the μ DMA controller copies data from the source buffer C to the peripheral data register.

8.2.7 Transfer Size and Increment

The μ DMA controller supports transfer data sizes of 8, 16, or 32 bits. The source and destination data size must be the same for any given transfer. The source and destination address can be auto-incremented by bytes, half-words, or words, or can be set to no increment. The source and destination address increment values can be set independently, and it is not necessary for the address increment to match the data size as long as the increment is the same or larger than the data size. For example, it is possible to perform a transfer using 8-bit data size, but using an address increment of full words (4 bytes). The data to be transferred must be aligned in memory according to the data size (8, 16, or 32 bits).

Table 8-5 on page 169 shows the configuration to read from a peripheral that supplies 8-bit data.

Table 8-5. μ DMA Read Example: 8-Bit Peripheral

Field	Configuration
Source data size	8 bits
Destination data size	8 bits
Source address increment	No increment
Destination address increment	Byte
Source end pointer	Peripheral read FIFO register
Destination end pointer	End of the data buffer in memory

8.2.8 Peripheral Interface

Each peripheral that supports μ DMA has a DMA single request and/or burst request signal that is asserted when the device is ready to transfer data. The request signal can be disabled or enabled by using the **DMA Channel Request Mask Set (DMAREQMASKSET)** and **DMA Channel Request Mask Clear (DMAREQMASKCLR)** registers. The DMA request signal is disabled, or masked, when the channel request mask bit is set. When the request is not masked, the DMA channel is configured correctly and enabled, and the peripheral asserts the DMA request signal, the μ DMA controller will begin the transfer.

When a DMA transfer is complete, the μ DMA controller asserts a DMA Done signal, which is routed through the interrupt vector of the peripheral. Therefore, if DMA is used to transfer data for a peripheral and interrupts are used, then the interrupt handler for that peripheral must be designed to handle the μ DMA transfer completion interrupt. When DMA is enabled for a peripheral, the μ DMA controller will mask the normal interrupts for a peripheral. This means that when a large amount of data is transferred using DMA, instead of receiving multiple interrupts from the peripheral as data flows, the processor will only receive one interrupt when the transfer is complete.

The interrupt request from the μ DMA controller is automatically cleared when the interrupt handler is activated.

8.2.9 Software Request

There is a dedicated μ DMA channel for software-initiated transfers. This channel also has a dedicated interrupt to signal completion of a DMA transfer. A transfer is initiated by software by first configuring and enabling the transfer, and then issuing a software request using the **DMA Channel Software Request (DMASWREQ)** register. For software-based transfers, the Auto transfer mode should be used.

It is possible to initiate a transfer on any channel using the **DMASWREQ** register. If a request is initiated by software using a peripheral DMA channel, then the completion interrupt will occur on the interrupt vector for the peripheral instead of the software interrupt vector. This means that any

channel may be used for software requests as long as the corresponding peripheral is not using μ DMA.

8.2.10 Interrupts and Errors

When a DMA transfer is complete, the μ DMA controller will generate a completion interrupt on the interrupt vector of the peripheral. If the transfer uses the software DMA channel, then the completion interrupt will occur on the dedicated software DMA interrupt vector.

If the μ DMA controller encounters a bus or memory protection error as it attempts to perform a data transfer, it will disable the DMA channel that caused the error, and generate an interrupt on the μ DMA Error interrupt vector. The processor can read the **DMA Bus Error Clear (DMAERRCLR)** register to determine if an error is pending. The `ERRCLR` bit will be set if an error occurred. The error can be cleared by writing a 1 to the `ERRCLR` bit.

Table 8-6 on page 170 shows the dedicated interrupt assignments for the μ DMA controller.

Table 8-6. μ DMA Interrupt Assignments

Interrupt	Assignment
46	μ DMA Software Channel Transfer
47	μ DMA Error

8.3 Initialization and Configuration

8.3.1 Module Initialization

Before the μ DMA controller can be used, it must be enabled in the System Control block and in the peripheral. The location of the channel control structure must also be programmed.

The following steps should be performed one time during system initialization:

1. The μ DMA peripheral must be enabled in the System Control block. To do this, set the `UDMA` bit of the System Control **RCGC2** register.
2. Enable the μ DMA controller by setting the `MASTEREN` bit of the **DMA Configuration (DMACFG)** register.
3. Program the location of the channel control table by writing the base address of the table to the **DMA Channel Control Base Pointer (DMACTLBASE)** register. The base address must be aligned on a 1024-byte boundary.

8.3.2 Configuring a Memory-to-Memory Transfer

μ DMA channel 30 is dedicated for software-initiated transfers. However, any channel can be used for software-initiated, memory-to-memory transfer if the associated peripheral is not being used.

8.3.2.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Set bit 30 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 30 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.

3. Set bit 30 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μ DMA controller to respond to single and burst requests.
4. Set bit 30 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μ DMA controller to recognize requests for this channel.

8.3.2.2 Configure the Channel Control Structure

Now the channel control structure must be configured.

This example will transfer 256 32-bit words from one memory buffer to another. Channel 30 is used for a software transfer, and the control structure for channel 30 is at offset 0x1E0 of the channel control table. The channel control structure for channel 30 is located at the offsets shown in Table 8-7 on page 171.

Table 8-7. Channel Control Structure Offsets for Channel 30

Offset	Description
Control Table Base + 0x1E0	Channel 30 Source End Pointer
Control Table Base + 0x1E4	Channel 30 Destination End Pointer
Control Table Base + 0x1E8	Channel 30 Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive).

1. Set the source end pointer at offset 0x1E0 to the address of the source buffer + 0x3FC.
2. Set the destination end pointer at offset 0x1E4 to the address of the destination buffer + 0x3FC.

The control word at offset 0x1E8 must be programmed according to Table 8-8 on page 171.

Table 8-8. Channel Control Word Configuration for Memory Transfer Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	2	32-bit destination address increment
DSTSIZE	29:28	2	32-bit destination data size
SRCINC	27:26	2	32-bit source address increment
SRCSIZE	25:24	2	32-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	255	Transfer 256 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	2	Use Auto-request transfer mode

8.3.2.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 30 of the **DMA Channel Enable Set (DMAENASET)** register.
2. Issue a transfer request by setting bit 30 of the **DMA Channel Software Request (DMASWREQ)** register.

The DMA transfer will now take place. If the interrupt is enabled, then the processor will be notified by interrupt when the transfer is complete. If needed, the status can be checked by reading bit 30 of the **DMAENASET** register. This bit will be automatically cleared when the transfer is complete. The status can also be checked by reading the **XFERMODE** field of the channel control word at offset 0x1E8. This field will automatically be set to 0 at the end of the transfer.

8.3.3 Configuring a Peripheral for Simple Transmit

This example will set up the μ DMA controller to transmit a buffer of data to a peripheral. The peripheral has a transmit FIFO with a trigger level of 4. The example peripheral will use μ DMA channel 7.

8.3.3.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Set bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.
2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μ DMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μ DMA controller to recognize requests for this channel.

8.3.3.2 Configure the Channel Control Structure

Now the channel control structure must be configured. This example will transfer 64 8-bit bytes from a memory buffer to the peripheral's transmit FIFO register. This example uses μ DMA channel 7, and the control structure for channel 7 is at offset 0x070 of the channel control table. The channel control structure for channel 7 is located at the offsets shown in Table 8-9 on page 172.

Table 8-9. Channel Control Structure Offsets for Channel 7

Offset	Description
Control Table Base + 0x070	Channel 7 Source End Pointer
Control Table Base + 0x074	Channel 7 Destination End Pointer
Control Table Base + 0x078	Channel 7 Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Since the peripheral pointer does not change, it simply points to the peripheral's data register.

1. Set the source end pointer at offset 0x070 to the address of the source buffer + 0x3F.
2. Set the destination end pointer at offset 0x074 to the address of the peripheral's transmit FIFO register.

The control word at offset 0x078 must be programmed according to Table 8-10 on page 173.

Table 8-10. Channel Control Word Configuration for Peripheral Transmit Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	3	Destination address does not increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	0	8-bit source address increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	2	Arbitrates after 4 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	1	Use Basic transfer mode

Note: In this example, it is not important if the peripheral makes a single request or a burst request. Since the peripheral has a FIFO that will trigger at a level of 4, the arbitration size is set to 4. If the peripheral does make a burst request, then 4 bytes will be transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any space in the FIFO), then one byte will be transferred at a time. If it is important to the application that transfers only be made in bursts, then the channel useburst `SET[n]` bit should be set by writing a 1 to bit 7 of the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

8.3.3.3 Start the Transfer

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 7 of the **DMA Channel Enable Set (DMAENASET)** register.

The μ DMA controller is now configured for transfer on channel 7. The controller will make transfers to the peripheral whenever the peripheral asserts a DMA request. The transfers will continue until the entire buffer of 64 bytes has been transferred. When that happens, the μ DMA controller will disable the channel and set the `XFERMODE` field of the channel control word to 0 (Stopped). The status of the transfer can be checked by reading bit 7 of the **DMA Channel Enable Set (DMAENASET)** register. This bit will be automatically cleared when the transfer is complete. The status can also be checked by reading the `XFERMODE` field of the channel control word at offset 0x078. This field will automatically be set to 0 at the end of the transfer.

If peripheral interrupts were enabled, then the peripheral interrupt handler would receive an interrupt when the entire transfer was complete.

8.3.4 Configuring a Peripheral for Ping-Pong Receive

This example will set up the μ DMA controller to continuously receive 8-bit data from a peripheral into a pair of 64 byte buffers. The peripheral has a receive FIFO with a trigger level of 8. The example peripheral will use μ DMA channel 8.

8.3.4.1 Configure the Channel Attributes

First, configure the channel attributes:

1. Set bit 7 of the **DMA Channel Priority Set (DMAPRIOSET)** or **DMA Channel Priority Clear (DMAPRIOCLR)** registers to set the channel to High priority or Default priority.

2. Set bit 7 of the **DMA Channel Primary Alternate Clear (DMAALTCLR)** register to select the primary channel control structure for this transfer.
3. Set bit 7 of the **DMA Channel Useburst Clear (DMAUSEBURSTCLR)** register to allow the μ DMA controller to respond to single and burst requests.
4. Set bit 7 of the **DMA Channel Request Mask Clear (DMAREQMASKCLR)** register to allow the μ DMA controller to recognize requests for this channel.

8.3.4.2 Configure the Channel Control Structure

Now the channel control structure must be configured. This example will transfer 8-bit bytes from the peripheral's receive FIFO register into two memory buffers of 64 bytes each. As data is received, when one buffer is full, the μ DMA controller switches to use the other.

To use Ping-Pong buffering, both primary and alternate channel control structures must be used. The primary control structure for channel 8 is at offset 0x080 of the channel control table, and the alternate channel control structure is at offset 0x280. The channel control structures for channel 8 are located at the offsets shown in Table 8-11 on page 174.

Table 8-11. Primary and Alternate Channel Control Structure Offsets for Channel 8

Offset	Description
Control Table Base + 0x080	Channel 8 Primary Source End Pointer
Control Table Base + 0x084	Channel 8 Primary Destination End Pointer
Control Table Base + 0x088	Channel 8 Primary Control Word
Control Table Base + 0x280	Channel 8 Alternate Source End Pointer
Control Table Base + 0x284	Channel 8 Alternate Destination End Pointer
Control Table Base + 0x288	Channel 8 Alternate Control Word

Configure the Source and Destination

The source and destination end pointers must be set to the last address for the transfer (inclusive). Since the peripheral pointer does not change, it simply points to the peripheral's data register. Both the primary and alternate sets of pointers must be configured.

1. Set the primary source end pointer at offset 0x080 to the address of the peripheral's receive buffer.
2. Set the primary destination end pointer at offset 0x084 to the address of ping-pong buffer A + 0x3F.
3. Set the alternate source end pointer at offset 0x280 to the address of the peripheral's receive buffer.
4. Set the alternate destination end pointer at offset 0x284 to the address of ping-pong buffer B + 0x3F.

The primary control word at offset 0x088, and the alternate control word at offset 0x288 must be programmed according to Table 8-10 on page 173. Both control words are initially programmed the same way.

1. Program the primary channel control word at offset 0x088 according to Table 8-12 on page 175.
2. Program the alternate channel control word at offset 0x288 according to Table 8-12 on page 175.

Table 8-12. Channel Control Word Configuration for Peripheral Ping-Pong Receive Example

Field in DMACHCTL	Bits	Value	Description
DSTINC	31:30	0	8-bit destination address increment
DSTSIZE	29:28	0	8-bit destination data size
SRCINC	27:26	3	Source address does not increment
SRCSIZE	25:24	0	8-bit source data size
reserved	23:18	0	Reserved
ARBSIZE	17:14	3	Arbitrates after 8 transfers
XFERSIZE	13:4	63	Transfer 64 items
NXTUSEBURST	3	0	N/A for this transfer type
XFERMODE	2:0	3	Use Ping-Pong transfer mode

Note: In this example, it is not important if the peripheral makes a single request or a burst request. Since the peripheral has a FIFO that will trigger at a level of 8, the arbitration size is set to 8. If the peripheral does make a burst request, then 8 bytes will be transferred, which is what the FIFO can accommodate. If the peripheral makes a single request (if there is any data in the FIFO), then one byte will be transferred at a time. If it is important to the application that transfers only be made in bursts, then the channel useburst `SET[n]` bit should be set by writing a 1 to bit 8 of the **DMA Channel Useburst Set (DMAUSEBURSTSET)** register.

8.3.4.3 Configure the Peripheral Interrupt

In order to use μ DMA Ping-Pong mode, it is best to use an interrupt handler. (It is also possible to use ping-pong mode without interrupts by polling). The interrupt handler will be triggered after each buffer is complete.

1. Configure and enable an interrupt handler for the peripheral.

8.3.4.4 Enable the μ DMA Channel

Now the channel is configured and is ready to start.

1. Enable the channel by setting bit 8 of the **DMA Channel Enable Set (DMAENASET)** register.

8.3.4.5 Process Interrupts

The μ DMA controller is now configured and enabled for transfer on channel 8. When the peripheral asserts the DMA request signal, the μ DMA controller will make transfers into buffer A using the primary channel control structure. When the primary transfer to buffer A is complete, it will switch to the alternate channel control structure and make transfers into buffer B. At the same time, the primary channel control word mode field will be set to indicate Stopped, and an interrupt will be triggered.

When an interrupt is triggered, the interrupt handler must determine which buffer is complete and process the data, or set a flag that the data needs to be processed by non-interrupt buffer processing code. Then the next buffer transfer must be set up.

In the interrupt handler:

1. Read the primary channel control word at offset 0x088 and check the `XFERMODE` field. If the field is 0, this means buffer A is complete. If buffer A is complete, then:

- a. Process the newly received data in buffer A, or signal the buffer processing code that buffer A has data available.
 - b. Reprogram the primary channel control word at offset 0x88 according to Table 8-12 on page 175.
2. Read the alternate channel control word at offset 0x288 and check the `XFERMODE` field. If the field is 0, this means buffer B is complete. If buffer B is complete, then:
 - a. Process the newly received data in buffer B, or signal the buffer processing code that buffer B has data available.
 - b. Reprogram the alternate channel control word at offset 0x288 according to Table 8-12 on page 175.

8.4 Register Map

Table 8-13 on page 176 lists the μ DMA channel control structures and registers. The channel control structure shows the layout of one entry in the channel control table. The channel control table is located in system memory, and the location is determined by the application, that is, the base address is n/a (not applicable). In the table below, the offset for the channel control structures is the offset from the entry in the channel control table. See “Channel Configuration” on page 159 and Table 8-3 on page 160 for a description of how the entries in the channel control table are located in memory. The μ DMA register addresses are given as a hexadecimal increment, relative to the μ DMA base address of 0x400F.F000.

Table 8-13. μ DMA Register Map

8.5 μ DMA Channel Control Structure

The μ DMA Channel Control Structure holds the DMA transfer settings for a DMA channel. Each channel has two control structures, which are located in a table in system memory. Refer to “Channel Configuration” on page 159 for an explanation of the Channel Control Table and the Channel Control Structure.

The channel control structure is one entry in the channel control table. There is a primary and alternate structure for each channel. The primary control structures are located at offsets 0x0, 0x10, 0x20 and so on. The alternate control structures are located at offsets 0x200, 0x210, 0x220, and so on.

Register 1: DMA Channel Source Address End Pointer (DMASRCENDP), offset 0x000

DMA Channel Source Address End Pointer (DMASRCENDP) is part of the Channel Control Structure, and is used to specify the source address for a DMA transfer.

DMA Channel Source Address End Pointer (DMASRCENDP)

Base n/a
 Offset 0x000
 Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Source Address End Pointer Points to the last address of the DMA transfer source (inclusive). If the source address is not incrementing, then this points at the source location itself (such as a peripheral data register).

Register 2: DMA Channel Destination Address End Pointer (DMADSTENDP), offset 0x004

DMA Channel Destination Address End Pointer (DMADSTENDP) is part of the Channel Control Structure, and is used to specify the destination address for a DMA transfer.

DMA Channel Destination Address End Pointer (DMADSTENDP)

Base n/a
Offset 0x004
Type R/W, reset -

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	R/W	-	Destination Address End Pointer Points to the last address of the DMA transfer destination (inclusive). If the destination address is not incrementing, then this points at the destination location itself (such as a peripheral data register).

Register 3: DMA Channel Control Word (DMACHCTL), offset 0x008

DMA Channel Control Word (DMACHCTL) is part of the Channel Control Structure, and is used to specify parameters of a DMA transfer.

DMA Channel Control Word (DMACHCTL)

Base n/a
Offset 0x008
Type R/W, reset -

Bit/Field	Name	Type	Reset	Description												
31:30	DSTINC	R/W	-	<p>Destination Address Increment</p> <p>Sets the bits to control the destination address increment.</p> <p>The address increment value must be equal or greater than the value of the destination size (DSTSIZE).</p> <p>Value Description</p> <table border="0"> <tr> <td>0x0</td> <td>Byte</td> <td>Increment by 8-bit locations.</td> </tr> <tr> <td>0x1</td> <td>Half-word</td> <td>Increment by 16-bit locations.</td> </tr> <tr> <td>0x2</td> <td>Word</td> <td>Increment by 32-bit locations.</td> </tr> <tr> <td>0x3</td> <td>No increment</td> <td>Address remains set to the value of the Destination Address End Pointer (DMADSTENDP) for the channel.</td> </tr> </table>	0x0	Byte	Increment by 8-bit locations.	0x1	Half-word	Increment by 16-bit locations.	0x2	Word	Increment by 32-bit locations.	0x3	No increment	Address remains set to the value of the Destination Address End Pointer (DMADSTENDP) for the channel.
0x0	Byte	Increment by 8-bit locations.														
0x1	Half-word	Increment by 16-bit locations.														
0x2	Word	Increment by 32-bit locations.														
0x3	No increment	Address remains set to the value of the Destination Address End Pointer (DMADSTENDP) for the channel.														
29:28	DSTSIZE	R/W	-	<p>Destination Data Size</p> <p>Sets the destination item data size.</p> <p>Note: You must set DSTSIZE to be the same as SRCSIZE.</p> <p>Value Description</p> <table border="0"> <tr> <td>0x0</td> <td>Byte</td> <td>8-bit data size.</td> </tr> <tr> <td>0x1</td> <td>Half-word</td> <td>16-bit data size.</td> </tr> <tr> <td>0x2</td> <td>Word</td> <td>32-bit data size.</td> </tr> <tr> <td>0x3</td> <td>Reserved</td> <td></td> </tr> </table>	0x0	Byte	8-bit data size.	0x1	Half-word	16-bit data size.	0x2	Word	32-bit data size.	0x3	Reserved	
0x0	Byte	8-bit data size.														
0x1	Half-word	16-bit data size.														
0x2	Word	32-bit data size.														
0x3	Reserved															

Bit/Field	Name	Type	Reset	Description										
27:26	SRCINC	R/W	-	<p>Source Address Increment</p> <p>Sets the bits to control the source address increment.</p> <p>The address increment value must be equal or greater than the value of the source size (<code>SRCSIZE</code>).</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Byte Increment by 8-bit locations.</td> </tr> <tr> <td>0x1</td> <td>Half-word Increment by 16-bit locations.</td> </tr> <tr> <td>0x2</td> <td>Word Increment by 32-bit locations.</td> </tr> <tr> <td>0x3</td> <td>No increment Address remains set to the value of the Source Address End Pointer (<code>DMASRCENDEP</code>) for the channel.</td> </tr> </tbody> </table>	Value	Description	0x0	Byte Increment by 8-bit locations.	0x1	Half-word Increment by 16-bit locations.	0x2	Word Increment by 32-bit locations.	0x3	No increment Address remains set to the value of the Source Address End Pointer (<code>DMASRCENDEP</code>) for the channel.
Value	Description													
0x0	Byte Increment by 8-bit locations.													
0x1	Half-word Increment by 16-bit locations.													
0x2	Word Increment by 32-bit locations.													
0x3	No increment Address remains set to the value of the Source Address End Pointer (<code>DMASRCENDEP</code>) for the channel.													
25:24	SRCSIZE	R/W	-	<p>Source Data Size</p> <p>Sets the source item data size.</p> <p>Note: You must set <code>DSTSIZE</code> to be the same as <code>SRCSIZE</code>.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>Byte 8-bit data size.</td> </tr> <tr> <td>0x1</td> <td>Half-word 16-bit data size.</td> </tr> <tr> <td>0x2</td> <td>Word 32-bit data size.</td> </tr> <tr> <td>0x3</td> <td>Reserved</td> </tr> </tbody> </table>	Value	Description	0x0	Byte 8-bit data size.	0x1	Half-word 16-bit data size.	0x2	Word 32-bit data size.	0x3	Reserved
Value	Description													
0x0	Byte 8-bit data size.													
0x1	Half-word 16-bit data size.													
0x2	Word 32-bit data size.													
0x3	Reserved													
23:18	reserved	R/W	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.										

Bit/Field	Name	Type	Reset	Description																										
17:14	ARBSIZE	R/W	-	<p>Arbitration Size</p> <p>Sets the number of DMA transfers that can occur before the controller re-arbitrates. The possible arbitration rate settings represent powers of 2 and are shown below.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>1 Transfer</td> </tr> <tr> <td></td> <td>Arbitrates after each DMA transfer.</td> </tr> <tr> <td>0x1</td> <td>2 Transfers</td> </tr> <tr> <td>0x2</td> <td>4 Transfers</td> </tr> <tr> <td>0x3</td> <td>8 Transfers</td> </tr> <tr> <td>0x4</td> <td>16 Transfers</td> </tr> <tr> <td>0x5</td> <td>32 Transfers</td> </tr> <tr> <td>0x6</td> <td>64 Transfers</td> </tr> <tr> <td>0x7</td> <td>128 Transfers</td> </tr> <tr> <td>0x8</td> <td>256 Transfers</td> </tr> <tr> <td>0x9</td> <td>512 Transfers</td> </tr> <tr> <td>0xA-0xF</td> <td>1024 Transfers</td> </tr> </tbody> </table> <p>This means that no arbitration occurs during the DMA transfer because the maximum transfer size is 1024.</p>	Value	Description	0x0	1 Transfer		Arbitrates after each DMA transfer.	0x1	2 Transfers	0x2	4 Transfers	0x3	8 Transfers	0x4	16 Transfers	0x5	32 Transfers	0x6	64 Transfers	0x7	128 Transfers	0x8	256 Transfers	0x9	512 Transfers	0xA-0xF	1024 Transfers
Value	Description																													
0x0	1 Transfer																													
	Arbitrates after each DMA transfer.																													
0x1	2 Transfers																													
0x2	4 Transfers																													
0x3	8 Transfers																													
0x4	16 Transfers																													
0x5	32 Transfers																													
0x6	64 Transfers																													
0x7	128 Transfers																													
0x8	256 Transfers																													
0x9	512 Transfers																													
0xA-0xF	1024 Transfers																													
13:4	XFERSIZE	R/W	-	<p>Transfer Size (minus 1)</p> <p>Sets the total number of items to transfer. The value of this field is 1 less than the number to transfer (value 0 means transfer 1 item). The maximum value for this 10-bit field is 1023 which represents a transfer size of 1024 items.</p> <p>The transfer size is the number of items, not the number of bytes. If the data size is 32 bits, then this value is the number of 32-bit words to transfer.</p> <p>The controller updates this field immediately prior to it entering the arbitration process, so it contains the number of outstanding DMA items that are necessary to complete the DMA cycle.</p>																										
3	NXTUSEBURST	R/W	-	<p>Next Useburst</p> <p>Controls whether the useburst <code>SET[n]</code> bit is automatically set for the last transfer of a peripheral scatter-gather operation. Normally, for the last transfer, if the number of remaining items to transfer is less than the arbitration size, the controller will use single transfers to complete the transaction. If this bit is set, then the controller will only use a burst transfer to complete the last transfer.</p>																										

Bit/Field	Name	Type	Reset	Description
2:0	XFERMODE	R/W	-	<p>DMA Transfer Mode</p> <p>Since this register is in system RAM, it has no reset value. Therefore, this field should be initialized to 0 before the channel is enabled.</p> <p>The operating mode of the DMA cycle. Refer to "Transfer Modes" on page 161 for a detailed explanation of transfer modes.</p> <p>Value Description</p> <p>0x0 Stop Channel is stopped, or configuration data is invalid.</p> <p>0x1 Basic The controller must receive a new request, prior to it entering the arbitration process, to enable the DMA cycle to complete.</p> <p>0x2 Auto-Request The initial request (software- or peripheral-initiated) is sufficient to complete the entire transfer of <i>XFERSIZE</i> items without any further requests.</p> <p>0x3 Ping-Pong The controller performs a DMA cycle using one of the channel control structures. After the DMA cycle completes, it performs a DMA cycle using the other channel control structure. After the next DMA cycle completes (and provided that the host processor has updated the original channel control data structure), it performs a DMA cycle using the original channel control data structure. The controller continues to perform DMA cycles until it either reads an invalid data structure or the host processor changes this field to 0x1 or 0x2. See "Ping-Pong" on page 161.</p> <p>0x4 Memory Scatter-Gather When the controller operates in Memory Scatter-Gather mode, you must only use this value in the primary channel control data structure. See "Memory Scatter-Gather" on page 162.</p> <p>0x5 Alternate Memory Scatter-Gather When the controller operates in Memory Scatter-Gather mode, you must only use this value in the alternate channel control data structure.</p> <p>0x6 Peripheral Scatter-Gather When the controller operates in Peripheral Scatter-Gather mode, you must only use this value in the primary channel control data structure. See "Peripheral Scatter-Gather" on page 166.</p> <p>0x7 Alternate Peripheral Scatter-Gather When the controller operates in Peripheral Scatter-Gather mode, you must only use this value in the alternate channel control data structure.</p>

8.6 μ DMA Register Descriptions

The register addresses given are relative to the μ DMA base address of 0x400F.F000.

Register 4: DMA Status (DMASTAT), offset 0x000

The **DMA Status (DMASTAT)** register returns the status of the controller. You cannot read this register when the controller is in the reset state.

DMA Status (DMASTAT)

Base 0x400F.F000
 Offset 0x000
 Type RO, reset 0x001F.0000

Bit/Field	Name	Type	Reset	Description
31:21	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
20:16	DMACHANS	RO	0x1F	Available DMA Channels Minus 1 This bit contains a value equal to the number of DMA channels the controller is configured to use, minus one. That is, 32 DMA channels.
15:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description																																						
7:4	STATE	RO	0x00	<p>Control State Machine State</p> <p>Current state of the control state machine. Register 5: DMA Configuration (DMACFG), offset 0x004

The **DMACFG** register controls the configuration of the controller.

DMA Configuration (DMACFG)

Base 0x400F.F000

Offset 0x004

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:1	reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	MASTEN	WO	-	Controller Master Enable Enables the controller.
				Value Description
				0 Disables
				1 Enables

Register 6: DMA Channel Control Base Pointer (DMACTLBASE), offset 0x008

The **DMACTLBASE** register must be configured so that the base pointer points to a location in system memory.

The amount of system memory that you must assign to the controller depends on the number of DMA channels used and whether you configure it to use the alternate channel control data structure. See “Channel Configuration” on page 159 for details about the Channel Control Table. The base address must be aligned on a 1024-byte boundary. You cannot read this register when the controller is in the reset state.

DMA Channel Control Base Pointer (DMACTLBASE)

Base 0x400F.F000

Offset 0x008

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADDR															
Type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADDR						reserved									
Type	R/W	R/W	R/W	R/W	R/W	R/W	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:10	ADDR	R/W	0x00	Channel Control Base Address Pointer to the base address of the channel control table. The base address must be 1024-byte aligned.
9:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 7: DMA Alternate Channel Control Base Pointer (DMAALTBASE), offset 0x00C

The **DMAALTBASE** register returns the base address of the alternate channel control data. This register removes the necessity for application software to calculate the base address of the alternate channel control structures. You cannot read this register when the controller is in the reset state.

DMA Alternate Channel Control Base Pointer (DMAALTBASE)

Base 0x400F.F000
 Offset 0x00C
 Type RO, reset 0x0000.0200

Bit/Field	Name	Type	Reset	Description
31:0	ADDR	RO	0x200	Alternate Channel Address Pointer Provides the base address of the alternate channel control structures.

Register 8: DMA Channel Wait on Request Status (DMAWAITSTAT), offset 0x010

This read-only register indicates that the μ DMA channel is waiting on a request. A peripheral can pull this Low to hold off the μ DMA from performing a single request until the peripheral is ready for a burst request. The use of this feature is dependent on the design of the peripheral and is used to enhance performance of the μ DMA with that peripheral. You cannot read this register when the controller is in the reset state.

DMA Channel Wait on Request Status (DMAWAITSTAT)

Base 0x400F.F000
Offset 0x010
Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	WAITREQ[n]	RO	0x00	Channel [n] Wait Status

Channel wait on request status. For each channel 0 through 31, a 1 in the corresponding bit field indicates that the channel is waiting on a request.

Register 9: DMA Channel Software Request (DMASWREQ), offset 0x014

Each bit of the **DMASWREQ** register represents the corresponding DMA channel. When you set a bit, it generates a request for the specified DMA channel.

DMA Channel Software Request (DMASWREQ)

Base 0x400F.F000

Offset 0x014

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	SWREQ[n]	WO	-	Channel [n] Software Request
------	----------	----	---	------------------------------

For each channel 0 through 31, write a 1 to the corresponding bit field to generate a software DMA request for that DMA channel. Writing a 0 does not create a DMA request for the corresponding channel.

Register 10: DMA Channel Useburst Set (DMAUSEBURSTSET), offset 0x018

Each bit of the **DMAUSEBURSTSET** register represents the corresponding DMA channel. Writing a 1 disables the peripheral's single request input from generating requests, and therefore only the peripheral's burst request generates requests. Reading the register returns the status of useburst.

When there are fewer items remaining to transfer than the arbitration (burst) size, the controller automatically clears the useburst bit to 0. This enables the remaining items to transfer using single requests. This bit should not be set for a peripheral's channel that does not support the burst request model.

Refer to “Request Types” on page 158 for more details about request types.

DMAUSEBURSTSET Reads

DMA Channel Useburst Set (DMAUSEBURSTSET)

Base 0x400F.F000
 Offset 0x018
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	R	0x00	Channel [n] Useburst Set Returns the useburst status of channel [n].
Value Description				
	0	Single and Burst DMA channel [n] responds to single or burst requests.		
	1	Burst Only DMA channel [n] responds only to burst requests.		

DMAUSEBURSTSET Writes

DMA Channel Useburst Set (DMAUSEBURSTSET)

Base 0x400F.F000
 Offset 0x018
 Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:0	SET[n]	W	0x00	Channel [n] Useburst Set Sets useburst bit on channel [n].

Value	Description
0	No Effect Use the DMAUSEBURSTCLR register to clear bit [n] to 0.
1	Burst Only DMA channel [n] responds only to burst requests.

Register 11: DMA Channel Useburst Clear (DMAUSEBURSTCLR), offset 0x01C

Each bit of the **DMAUSEBURSTCLR** register represents the corresponding DMA channel. Writing a 1 enables `dma_sreq[n]` to generate requests.

DMA Channel Useburst Clear (DMAUSEBURSTCLR)

Base 0x400F.F000

Offset 0x01C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	CLR[n]	WO	-	Channel [n] Useburst Clear Clears useburst bit on channel [n].
				Value Description
				0 No Effect
				Use the DMAUSEBURSTSET to set bit [n] to 1.
				1 Single and Burst
				DMA channel [n] responds to single and burst requests.

Register 12: DMA Channel Request Mask Set (DMAREQMASKSET), offset 0x020

Each bit of the **DMAREQMASKSET** register represents the corresponding DMA channel. Writing a 1 disables DMA requests for the channel. Reading the register returns the request mask status. When a μ DMA channel's request is masked, that means the peripheral can no longer request μ DMA transfers. The channel can then be used for software-initiated transfers.

9 General-Purpose Input/Outputs (GPIOs)

The GPIO module is composed of five physical GPIO blocks, each corresponding to an individual GPIO port (Port A, Port B, Port C, Port D, and Port E,). The GPIO module supports 3-33 programmable input/output pins, depending on the peripherals being used.

The GPIO module has the following features:

- Two means of port access: either high speed (for single-cycle writes), or legacy for backwards-compatibility with existing code
- Programmable control for GPIO interrupts
 - Interrupt generation masking
 - Edge-triggered on rising, falling, or both
 - Level-sensitive on High or Low values
- 5-V-tolerant input/outputs
- Bit masking in both read and write operations through address lines
- Pins configured as digital inputs are Schmitt-triggered.
- Programmable control for GPIO pad configuration:
 - Weak pull-up or pull-down resistors
 - 2-mA, 4-mA, and 8-mA pad drive for digital communication; up to four pads can be configured with an 18-mA pad drive for high-current applications
 - Slew rate control for the 8-mA drive
 - Open drain enables
 - Digital input enables

9.1 Functional Description

Important: All GPIO pins are tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**), with the exception of the four JTAG/SWD pins ($PC[3:0]$). The JTAG/SWD pins default to their JTAG/SWD functionality (**GPIOAFSEL=1**, **GPIODEN=1** and **GPIOPUR=1**). A Power-On-Reset (\overline{POR}) or asserting \overline{RST} puts both groups of pins back to their default state.

Each GPIO port is a separate hardware instantiation of the same physical block(see Figure 9-1 on page 218 and Figure 9-2 on page 219). The LM3S2671 microcontroller contains five ports and thus five of these physical GPIO blocks.

Figure 9-1. Digital I/O Pads

Figure 9-2. Analog/Digital I/O Pads

9.1.1 Data Control

The data control registers allow software to configure the operational modes of the GPIOs. The data direction register configures the GPIO as an input or an output while the data register either captures incoming data or drives it out to the pads.

9.1.1.1 Data Direction Operation

The **GPIO Direction (GPIODIR)** register (see page 227) is used to configure each individual pin as an input or output. When the data direction bit is set to 0, the GPIO is configured as an input and the corresponding data register bit will capture and store the value on the GPIO port. When the data direction bit is set to 1, the GPIO is configured as an output and the corresponding data register bit will be driven out on the GPIO port.

9.1.1.2 Data Register Operation

To aid in the efficiency of software, the GPIO ports allow for the modification of individual bits in the **GPIO Data (GPIODATA)** register (see page 226) by using bits [9:2] of the address bus as a mask. This allows software drivers to modify individual GPIO pins in a single instruction, without affecting the state of the other pins. This is in contrast to the "typical" method of doing a read-modify-write operation to set or clear an individual GPIO pin. To accommodate this feature, the **GPIODATA** register covers 256 locations in the memory map.

During a write, if the address bit associated with that data bit is set to 1, the value of the **GPIODATA** register is altered. If it is cleared to 0, it is left unchanged.

For example, writing a value of 0xEB to the address **GPIODATA + 0x098** would yield as shown in Figure 9-3 on page 220, where *u* is data unchanged by the write.

Figure 9-3. GPIODATA Write Example

During a read, if the address bit associated with the data bit is set to 1, the value is read. If the address bit associated with the data bit is set to 0, it is read as a zero, regardless of its actual value. For example, reading address **GPIODATA + 0x0C4** yields as shown in Figure 9-4 on page 220.

Figure 9-4. GPIODATA Read Example

9.1.2 Interrupt Control

The interrupt capabilities of each GPIO port are controlled by a set of seven registers. With these registers, it is possible to select the source of the interrupt, its polarity, and the edge properties. When one or more GPIO inputs cause an interrupt, a single interrupt output is sent to the interrupt controller for the entire GPIO port. For edge-triggered interrupts, software must clear the interrupt to enable any further interrupts. For a level-sensitive interrupt, it is assumed that the external source holds the level constant for the interrupt to be recognized by the controller.

Three registers are required to define the edge or sense that causes interrupts:

- **GPIO Interrupt Sense (GPIOIS)** register (see page 228)
- **GPIO Interrupt Both Edges (GPIOIBE)** register (see page 229)
- **GPIO Interrupt Event (GPIOIEV)** register (see page 230)

Interrupts are enabled/disabled via the **GPIO Interrupt Mask (GPIOIM)** register (see page 231).

When an interrupt condition occurs, the state of the interrupt signal can be viewed in two locations: the **GPIO Raw Interrupt Status (GPIORIS)** and **GPIO Masked Interrupt Status (GPIOMIS)** registers (see page 232 and page 233). As the name implies, the **GPIOMIS** register only shows interrupt

conditions that are allowed to be passed to the controller. The **GPIORIS** register indicates that a GPIO pin meets the conditions for an interrupt, but has not necessarily been sent to the controller.

In addition to providing GPIO functionality, $PB4$ can also be used as an external trigger for the ADC. If $PB4$ is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set to 1), not only is an interrupt for PortB generated, but an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated.

If no other PortB pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETNA) register can disable the PortB interrupts and the ADC interrupt can be used to read back the converted data. Otherwise, the PortB interrupt handler needs to ignore and clear interrupts on $B4$, and wait for the ADC interrupt or the ADC interrupt needs to be disabled in the SETNA register and the PortB interrupt handler polls the ADC registers until the conversion is completed.

Interrupts are cleared by writing a 1 to the appropriate bit of the **GPIO Interrupt Clear (GPIOICR)** register (see page 234).

When programming the following interrupt control registers, the interrupts should be masked (**GPIOIM** set to 0). Writing any value to an interrupt control register (**GPIOIS**, **GPIOIBE**, or **GPIOIEV**) can generate a spurious interrupt if the corresponding bits are enabled.

9.1.3 Mode Control

The GPIO pins can be controlled by either hardware or software. When hardware control is enabled via the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 235), the pin state is controlled by its alternate function (that is, the peripheral). Software control corresponds to GPIO mode, where the **GPIODATA** register is used to read/write the corresponding pins.

Note: If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be written to 1 to disable the analog isolation circuit.

9.1.4 Commit Control

The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 235), **GPIO Pull-Up Select (GPIOPUR)** register (see page 241), and **GPIO Digital Enable (GPIODEN)** register (see page 244) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 246) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 247) have been set to 1.

9.1.5 Pad Control

The pad control registers allow for GPIO pad configuration by software based on the application requirements. The pad control registers include the **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR**, **GPIOPUR**, **GPIOPDR**, **GPIOSLR**, and **GPIODEN** registers. These registers control drive strength, open-drain configuration, pull-up and pull-down resistors, slew-rate control and digital input enable.

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the V_{OL} value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

9.1.6 Identification

The identification registers configured at reset allow software to detect and identify the module as a GPIO block. The identification registers include the **GPIOPeriphID0-GPIOPeriphID7** registers as well as the **GPIOCellID0-GPIOCellID3** registers.

9.2 Initialization and Configuration

The GPIO modules may be accessed via two different memory apertures. The legacy aperture is backwards-compatible with previous Stellaris parts and offers two-cycle access time to all GPIO registers. The high-speed aperture offers the same register map but provides single-cycle access times. These apertures are mutually exclusive. The aperture enabled for a given GPIO port is controlled by the appropriate bit in the **GPIOHCTL** register (see page 87).

To use the GPIO, the peripheral clock must be enabled by setting the appropriate GPIO Port bit field (**GPIO_n**) in the **RCGC2** register.

On reset, all GPIO pins (except for the four JTAG pins) are configured out of reset to be undriven (tristate): **GPIOAFSEL=0**, **GPIO DEN=0**, **GPIO PDR=0**, and **GPIO PUR=0**. Table 9-1 on page 222 shows all possible configurations of the GPIO pads and the control register settings required to achieve them. Table 9-2 on page 223 shows how a rising edge interrupt would be configured for pin 2 of a GPIO port.

Table 9-1. GPIO Pad Configuration Examples

Configuration	GPIO Register Bit Value ^a									
	AFSEL	DIR	ODR	DEN	PUR	PDR	DR2R	DR4R	DR8R	SLR

a. X=Ignored (don't care bit)

?=Can be either 0 or 1, depending on the configuration

Table 9-2. GPIO Interrupt Configuration Example

Register	Desired Interrupt Event Trigger	Pin 2 Bit Value ^a							
		7	6	5	4	3	2	1	0
GPIOIS	0=edge 1=level	X	X	X	X	X	0	X	X
GPIOIBE	0=single edge 1=both edges	X	X	X	X	X	0	X	X
GPIOIEV	0=Low level, or negative edge 1=High level, or positive edge	X	X	X	X	X	1	X	X
GPIOIM	0=masked 1=not masked	0	0	0	0	0	1	0	0

a. X=Ignored (don't care bit)

9.3 Register Map

Table 9-3 on page 224 lists the GPIO registers. The offset listed is a hexadecimal increment to the register's address, relative to that GPIO port's base address:

- GPIO Port A (legacy): 0x4000.4000
- GPIO Port A (high-speed): 0x4005.8000
- GPIO Port B (legacy): 0x4000.5000
- GPIO Port B (high-speed): 0x4005.9000
- GPIO Port C (legacy): 0x4000.6000
- GPIO Port C (high-speed): 0x4005.A000
- GPIO Port D (legacy): 0x4000.7000
- GPIO Port D (high-speed): 0x4005.B000
- GPIO Port E (legacy): 0x4002.4000
- GPIO Port E (high-speed): 0x4005.C000

Important: The GPIO registers in this chapter are duplicated in each GPIO block, however, depending on the block, all eight bits may not be connected to a GPIO pad. In those cases, writing to those unconnected bits has no effect and reading those unconnected bits returns no meaningful data.

Note: The default reset value for the **GPIOAFSEL**, **GPIOPUR**, and **GPIODEN** registers are 0x0000.0000 for all GPIO pins, with the exception of the four JTAG/SWD pins (PC[3:0]). These four pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for Port C is 0x0000.000F.

The default register type for the **GPIOCR** register is RO for all GPIO pins, with the exception of the **NMI** pin and the four JTAG/SWD pins (PB7 and PC[3:0]). These five pins are currently the only GPIOs that are protected by the **GPIOCR** register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.

The default reset value for the **GPIOCR** register is 0x0000.00FF for all GPIO pins, with the exception of the **NMI** pin and the four JTAG/SWD pins (PB7 and PC[3:0]). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the **NMI** pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset value of **GPIOCR** for GPIO Port B is 0x0000.007F while the default reset value of GPIOCR for Port C is 0x0000.00F0.

9.4 Register Descriptions

The remainder of this section lists and describes the GPIO registers, in numerical order by address offset.

Register 1: GPIO Data (GPIODATA), offset 0x000

The **GPIODATA** register is the data register. In software control mode, values written in the **GPIODATA** register are transferred onto the GPIO port pins if the respective pins have been configured as outputs through the **GPIO Direction (GPIODIR)** register (see page 227).

In order to write to **GPIODATA**, the corresponding bits in the mask, resulting from the address bus bits [9:2], must be High. Otherwise, the bit values remain unchanged by the write.

Similarly, the values read from this register are determined for each bit by the mask bit derived from the address used to access the data register, bits [9:2]. Bits that are 1 in the address mask cause the corresponding bits in **GPIODATA** to be read, and bits that are 0 in the address mask cause the corresponding bits in **GPIODATA** to be read as 0, regardless of their value.

A read from **GPIODATA** returns the last bit value written if the respective pins are configured as outputs, or it returns the value on the corresponding input pin when these are configured as inputs. All bits are cleared by a reset.

GPIO Data (GPIODATA)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000
 GPIO Port B (legacy) base: 0x4000.5000
 GPIO Port B (high-speed) base: 0x4005.9000
 GPIO Port C (legacy) base: 0x4000.6000
 GPIO Port C (high-speed) base: 0x4005.A000
 GPIO Port D (legacy) base: 0x4000.7000
 GPIO Port D (high-speed) base: 0x4005.B000
 GPIO Port E (legacy) base: 0x4002.4000
 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x000
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	R/W	0x00	GPIO Data

This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and the data written to the registers are masked by the eight address lines `ipaddr[9:2]`. Reads from this register return its current state. Writes to this register only affect bits that are not masked by `ipaddr[9:2]` and are configured as outputs. See "Data Register Operation" on page 219 for examples of reads and writes.

Register 2: GPIO Direction (GPIODIR), offset 0x400

The **GPIODIR** register is the data direction register. Bits set to 1 in the **GPIODIR** register configure the corresponding pin to be an output, while bits set to 0 configure the pins to be inputs. All bits are cleared by a reset, meaning all GPIO pins are inputs by default.

GPIO Direction (GPIODIR)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000
 GPIO Port B (legacy) base: 0x4000.5000
 GPIO Port B (high-speed) base: 0x4005.9000
 GPIO Port C (legacy) base: 0x4000.6000
 GPIO Port C (high-speed) base: 0x4005.A000
 GPIO Port D (legacy) base: 0x4000.7000
 GPIO Port D (high-speed) base: 0x4005.B000
 GPIO Port E (legacy) base: 0x4002.4000
 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x400
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DIR	R/W	0x00	GPIO Data Direction

The **DIR** values are defined as follows:

Value	Description
0	Pins are inputs.
1	Pins are outputs.

Register 3: GPIO Interrupt Sense (GPIOIS), offset 0x404

The **GPIOIS** register is the interrupt sense register. Bits set to 1 in **GPIOIS** configure the corresponding pins to detect levels, while bits set to 0 configure the pins to detect edges. All bits are cleared by a reset.

GPIO Interrupt Sense (GPIOIS)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000
 GPIO Port B (legacy) base: 0x4000.5000
 GPIO Port B (high-speed) base: 0x4005.9000

 GPIO Port E (legacy) base: 0x4002.4000
 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x404
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IS	R/W	0x00	GPIO Interrupt Sense

The **IS** values are defined as follows:

Value	Description
0	Edge on corresponding pin is detected (edge-sensitive).
1	Level on corresponding pin is detected (level-sensitive).

Register 4: GPIO Interrupt Both Edges (GPIOIBE), offset 0x408

The **GPIOIBE** register is the interrupt both-edges register. When the corresponding bit in the **GPIO Interrupt Sense (GPIOIS)** register (see page 228) is set to detect edges, bits set to High in **GPIOIBE** configure the corresponding pin to detect both rising and falling edges, regardless of the corresponding bit in the **GPIO Interrupt Event (GPIOIEV)** register (see page 230). Clearing a bit configures the pin to be controlled by **GPIOIEV**. All bits are cleared by a reset.

GPIO Interrupt Both Edges (GPIOIBE)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000

31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IBE	R/W	0x00	GPIO Interrupt Both Edges

The **IBE** values are defined as follows:

Value Description

- 0 Interrupt generation is controlled by the **GPIO Interrupt Event (GPIOIEV)** register (see page 230).
- 1 Both edges on the corresponding pin trigger an interrupt.

Note: Single edge is determined by the corresponding bit in **GPIOIEV**.

Register 5: GPIO Interrupt Event (GPIOIEV), offset 0x40C

The **GPIOIEV** register is the interrupt event register. Bits set to High in **GPIOIEV** configure the corresponding pin to detect rising edges or high levels, depending on the corresponding bit value in the **GPIO Interrupt Sense (GPIOIS)** register (see page 228). Clearing a bit configures the pin to detect falling edges or low levels, depending on the corresponding bit value in **GPIOIS**. All bits are cleared by a reset.

GPIO Interrupt Event (GPIOIEV)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000

 Offset 0x40C
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IEV	R/W	0x00	GPIO Interrupt Event

The **IEV** values are defined as follows:

Value	Description
0	Falling edge or Low levels on corresponding pins trigger interrupts.
1	Rising edge or High levels on corresponding pins trigger interrupts.

Register 6: GPIO Interrupt Mask (GPIOIM), offset 0x410

The **GPIOIM** register is the interrupt mask register. Bits set to High in **GPIOIM** allow the corresponding pins to trigger their individual interrupts and the combined **GPIOINTR** line. Clearing a bit disables interrupt triggering on that pin. All bits are cleared by a reset.

GPIO Interrupt Mask (GPIOIM)

7:0	IME	R/W	0x00	GPIO Interrupt Mask Enable

The **IME** values are defined as follows:

Value	Description
0	Corresponding pin interrupt is masked.
1	Corresponding pin interrupt is not masked.

Register 7: GPIO Raw Interrupt Status (GPIORIS), offset 0x414

The **GPIORIS** register is the raw interrupt status register. Bits read High in **GPIORIS** reflect the status of interrupt trigger conditions detected (raw, prior to masking), indicating that all the requirements have been met, before they are finally allowed to trigger by the **GPIO Interrupt Mask (GPIOIM)** register (see page 231). Bits read as zero indicate that corresponding input pins have not initiated an interrupt. All bits are cleared by a reset.

GPIO Raw Interrupt Status (GPIORIS)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000
 GPIO Port B (legacy) base: 0x4000.5000

 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x414
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	RIS	RO	0x00	GPIO Interrupt Raw Status Reflects the status of interrupt trigger condition detection on pins (raw, prior to masking).

The RIS values are defined as follows:

Value	Description
0	Corresponding pin interrupt requirements not met.
1	Corresponding pin interrupt has met requirements.

Register 8: GPIO Masked Interrupt Status (GPIOMIS), offset 0x418

The **GPIOMIS** register is the masked interrupt status register. Bits read High in **GPIOMIS** reflect the status of input lines triggering an interrupt. Bits read as Low indicate that either no interrupt has been generated, or the interrupt is masked.

In addition to providing GPIO functionality, **PB4** can also be used as an external trigger for the ADC. If **PB4** is configured as a non-masked interrupt pin (the appropriate bit of **GPIOIM** is set to 1), not only is an interrupt for PortB generated, but an external trigger signal is sent to the ADC. If the **ADC Event Multiplexer Select (ADCEMUX)** register is configured to use the external trigger, an ADC conversion is initiated.

If no other PortB pins are being used to generate interrupts, the ARM Integrated Nested Vectored Interrupt Controller (NVIC) Interrupt Set Enable (SETNA) register can disable the PortB interrupts and the ADC interrupt can be used to read back the converted data. Otherwise, the PortB interrupt handler needs to ignore and clear interrupts on **B4**, and wait for the ADC interrupt or the ADC interrupt needs to be disabled in the SETNA register and the PortB interrupt handler polls the ADC registers until the conversion is completed.

GPIOMIS is the state of the interrupt after masking.

GPIO Masked Interrupt Status (GPIOMIS)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000
 GPIO Port B (legacy) base: 0x4000.5000
 GPIO Port B (high-speed) base: 0x4005.9000
 GPIO Port C (legacy) base: 0x4000.6000

 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x418
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	MIS	RO	0x00	GPIO Masked Interrupt Status

Masked value of interrupt due to corresponding pin.

The **MIS** values are defined as follows:

Value	Description
0	Corresponding GPIO line interrupt not active.
1	Corresponding GPIO line asserting interrupt.

Register 9: GPIO Interrupt Clear (GPIOICR), offset 0x41C

The **GPIOICR** register is the interrupt clear register. Writing a 1 to a bit in this register clears the corresponding interrupt edge detection logic register. Writing a 0 has no effect.

GPIO Interrupt Clear (GPIOICR)

GPIO Port A (legacy) base: 0x4000.4000
 GPIO Port A (high-speed) base: 0x4005.8000
 GPIO Port B (legacy) base: 0x4000.5000
 GPIO Port B (high-speed) base: 0x4005.9000
 GPIO Port C (legacy) base: 0x4000.6000
 GPIO Port C (high-speed) base: 0x4005.A000

 GPIO Port E (legacy) base: 0x4002.4000
 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x41C
 Type W1C, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	IC	W1C	0x00	GPIO Interrupt Clear

The IC values are defined as follows:

Value	Description
0	Corresponding interrupt is unaffected.
1	Corresponding interrupt is cleared.

Register 10: GPIO Alternate Function Select (GPIOAFSEL), offset 0x420

The **GPIOAFSEL** register is the mode control select register. Writing a 1 to any bit in this register selects the hardware control for the corresponding GPIO line. All bits are cleared by a reset, therefore no GPIO line is set to hardware control by default.

The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 235), **GPIO Pull-Up Select (GPIOPUR)** register (see page 241), and **GPIO Digital Enable (GPIODEN)** register (see page 244) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 246) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 247) have been set to 1.

Important: All GPIO pins are tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, and **GPIOPUR=0**), with the exception of the four JTAG/SWD pins ($PC[3:0]$). The JTAG/SWD pins default to their JTAG/SWD functionality (**GPIOAFSEL=1**, **GPIODEN=1** and **GPIOPUR=1**). A Power-On-Reset (\overline{POR}) or asserting \overline{RST} puts both groups of pins back to their default state.

Caution – It is possible to create a software sequence that prevents the debugger from connecting to the Stellaris® microcontroller. If the program code loaded into flash immediately changes the JTAG pins to their GPIO functionality, the debugger may not have enough time to connect and halt the controller before the JTAG pin functionality switches. This may lock the debugger out of the part. This can be avoided with a software routine that restores JTAG functionality based on an external or software trigger.

GPIO Alternate Function Select (GPIOAFSEL)

Register 11: GPIO 2-mA Drive Select (GPIODR2R), offset 0x500

The **GPIODR2R** register is the 2-mA drive control register. It allows for each GPIO signal in the port to be individually configured without affecting the other pads. When writing a **DRV2** bit for a GPIO signal, the corresponding **DRV4** bit in the **GPIODR4R** register and the **DRV8** bit in the **GPIODR8R** register are automatically cleared by hardware.

GPIO 2-mA Drive Select (GPIODR2R)

 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x504
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DRV4	R/W	0x00	Output Pad 4-mA Drive Enable A write of 1 to either GPIODR2[n] or GPIODR8[n] clears the corresponding 4-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the legacy memory aperture. If using high-speed access, the change is effective on the next clock cycle.

Register 13: GPIO 8-mA Drive Select (GPIODR8R), offset 0x508

The **GPIODR8R** register is the 8-mA drive control register. It allows for each GPIO signal in the port to be individually configured without affecting the other pads. When writing the **DRV8** bit for a GPIO signal, the corresponding **DRV2** bit in the **GPIODR2R** register and the **DRV4** bit in the **GPIODR4R** register are automatically cleared by hardware. The 8-mA setting is also used for high-current operation.

Note: There is no configuration difference between 8-mA and high-current operation. The additional current capacity results from a shift in the V_{OH}/V_{OL} levels. See “Recommended DC Operating Conditions” on page 571 for further information.

GPIO 8-mA Drive Select (GPIODR8R)

GPIO Port A (legacy) base: 0x4000.4000

7:0	DRV8	R/W	0x00	Output Pad 8-mA Drive Enable A write of 1 to either GPIODR2[n] or GPIODR4[n] clears the corresponding 8-mA enable bit. The change is effective on the second clock cycle after the write if accessing GPIO via the legacy memory aperture. If using high-speed access, the change is effective on the next clock cycle.

Register 14: GPIO Open Drain Select (GPIOODR), offset 0x50C

The **GPIOODR** register is the open drain control register. Setting a bit in this register enables the open drain configuration of the corresponding GPIO pad. When open drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Input Enable (GPIODEN)** register (see page 244). Corresponding bits in the drive strength registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired rise and fall times. The GPIO acts as an open drain input if the corresponding bit in the **GPIODIR** register is set to 0; and as an open drain output when set to 1.

When using the I²C module, in addition to configuring the pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bit for the I²C clock and data pins should be set to 1 (see examples in “Initialization and Configuration” on page 222).

GPIO Open Drain Select (GPIOODR)

GPIO Port A (legacy) base: 0x4000.4000

7:0	ODE	R/W	0x00	Output Pad Open Drain Enable

The ODE values are defined as follows:

Value	Description
0	Open drain configuration is disabled.
1	Open drain configuration is enabled.

Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510

The **GPIOPUR** register is the pull-up control register. When a bit is set to 1, it enables a weak pull-up resistor on the corresponding GPIO signal. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 242). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are set to 0 will prevent writes to the equivalent bit in this register.

Note: The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 235), **GPIO Pull-Up Select (GPIOPUR)** register (see page 241), and **GPIO Digital Enable (GPIODEN)** register (see page 244) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 246) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 247) have been set to 1.

7:0	SRL	R/W	0x00	Slew Rate Limit Enable (8-mA drive only)
-----	-----	-----	------	--

The **SRL** values are defined as follows:

Value	Description
0	Slew rate control disabled.
1	Slew rate control enabled.

Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C

Note: Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, with the exception of the GPIO signals used for JTAG/SWD function, all other GPIO signals are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin in a digital function (either GPIO or alternate function), the corresponding **GPIODEN** bit must be set.

Note: The commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 235), **GPIO Pull-Up Select (GPIOPUR)** register (see page 241), and **GPIO Digital Enable (GPIODEN)** register (see page 244) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 246) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 247) have been set to 1.

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Bit/Field	Name	Type	Reset	Description
7:0	DEN	R/W	-	Digital Enable
				The DEN values are defined as follows:
				Value Description
				0 Digital functions disabled.
				1 Digital functions enabled.
				Note: The default reset value for the GPIOAFSEL , GPIOPUR , and GPIODEN registers are 0x0000.0000 for all GPIO pins, with the exception of the four JTAG/SWD pins (PC[3:0]). These four pins default to JTAG/SWD functionality. Because of this, the default reset value of these registers for Port C is 0x0000.000F.

Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 247). Writing 0x0x4C4F.434B to the **GPIOLOCK** register will unlock the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x00000001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x00000000.

GPIO Lock (GPIOLOCK)

GPIO Port A (legacy) base: 0x4000.4000

 GPIO Port D (legacy) base: 0x4000.7000
 GPIO Port D (high-speed) base: 0x4005.B000
 GPIO Port E (legacy) base: 0x4002.4000
 GPIO Port E (high-speed) base: 0x4005.C000
 Offset 0x520
 Type R/W, reset 0x0000.0001

Bit/Field	Name	Type	Reset	Description
31:0	LOCK	R/W	0x0000.0001	GPIO Lock

A write of the value 0x4C4F.434B unlocks the **GPIO Commit (GPIOCR)** register for write access.

A write of any other value or a write to the **GPIOCR** register reapplies the lock, preventing any register updates. A read of this register returns the following values:

Value	Description
0x0000.0001	locked
0x0000.0000	unlocked

Register 20: GPIO Commit (GPIOCR), offset 0x524

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, and **GIODEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is zero, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, or **GIODEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, or **GIODEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the **GPIOLOCK** register is locked.

Important: This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for **PB7** and **PC[3:0]**, the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins on **PB7** and **PC[3:0]**, all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, or **GIODEN** register bits of these other pins.

Bit/Field	Name	Type	Reset	Description
7:0	CR	-	-	<p>GPIO Commit</p> <p>On a bit-wise basis, any bit set allows the corresponding <code>GPIOAFSEL</code> bit to be set to its alternate function.</p> <p>Note: The default register type for the GPIOCR register is RO for all GPIO pins, with the exception of the <code>NMI</code> pin and the four JTAG/SWD pins (<code>PB7</code> and <code>PC[3:0]</code>). These five pins are currently the only GPIOs that are protected by the GPIOCR register. Because of this, the register type for GPIO Port B7 and GPIO Port C[3:0] is R/W.</p> <p>The default reset value for the GPIOCR register is 0x0000.00FF for all GPIO pins, with the exception of the <code>NMI</code> pin and the four JTAG/SWD pins (<code>PB7</code> and <code>PC[3:0]</code>). To ensure that the JTAG port is not accidentally programmed as a GPIO, these four pins default to non-committable. To ensure that the <code>NMI</code> pin is not accidentally programmed as the non-maskable interrupt pin, it defaults to non-committable. Because of this, the default reset value of GPIOCR for GPIO Port B is 0x0000.007F while the default reset value of GPIOCR for Port C is 0x0000.00F0.</p>

Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528

Note: If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be written to 1 to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 5V source and affect analog operation, analog circuitry requires isolation from the pins when not used in their analog function.

Each bit of this register controls the isolation circuitry for circuits that share the same pin as the GPIO bit lane.

Note: This register is only valid for ports D and E.

10 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The Stellaris[®] General-Purpose Timer Module (GPTM) contains four GPTM blocks (Timer0, Timer1, Timer 2, and Timer 3). Each GPTM block provides two 16-bit timers/counters (referred to as TimerA and TimerB) that can be configured to operate independently as timers or event counters, or configured to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger analog-to-digital (ADC) conversions. The trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The General-Purpose Timer Module is one timing resource available on the Stellaris[®] microcontrollers. Other timer resources include the System Timer (SysTick) (see “System Timer (SysTick)” on page 42) and the PWM timer in the PWM module (see “PWM Timer” on page 523).

The following modes are supported:

- 32-bit Timer modes
 - Programmable one-shot timer
 - Programmable periodic timer
 - Real-Time Clock using 32.768-KHz input clock
 - Software-controlled event stalling (excluding RTC mode)
- 16-bit Timer modes
 - General-purpose timer function with an 8-bit prescaler (for one-shot and periodic modes only)
 - Programmable one-shot timer
 - Programmable periodic timer
 - Software-controlled event stalling
- 16-bit Input Capture modes
 - Input edge count capture
 - Input edge time capture
- 16-bit PWM mode
 - Simple PWM mode with software-programmable output inversion of the PWM signal

10.1 Block Diagram

Note: In Figure 10-1 on page 263, the specific CCP pins available depend on the Stellaris[®] device. See Table 10-1 on page 263 for the available CCPs.

Figure 10-1. GPTM Module Block Diagram

Table 10-1. Available CCP Pins

Timer	16-Bit Up/Down Counter	Even CCP Pin	Odd CCP Pin
Timer 0	TimerA	CCP0	-
	TimerB	-	CCP1
Timer 1	TimerA	-	-
	TimerB	-	-
Timer 2	TimerA	-	-
	TimerB	-	-
Timer 3	TimerA	-	-
	TimerB	-	-

10.2 Functional Description

The main components of each GPTM block are two free-running 16-bit up/down counters (referred to as TimerA and TimerB), two 16-bit match registers, and two 16-bit load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface.

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 274), the **GPTM TimerA Mode (GPTMTAMR)** register (see page 275), and the **GPTM TimerB Mode (GPTMTBMR)** register (see page 277). When in one of the 32-bit modes, the timer can only act as a 32-bit timer. However, when configured in 16-bit mode, the GPTM can have its two 16-bit timers configured in any combination of the 16-bit modes.

10.2.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters TimerA and TimerB are initialized to 0xFFFF, along with their corresponding load registers: the **GPTM TimerA Interval Load (GPTMTAILR)** register (see page 288) and the **GPTM TimerB Interval Load (GPTMTBILR)** register (see page 289). The prescale counters are initialized to 0x00: the **GPTM TimerA Prescale (GPTMTAPR)** register (see page 292) and the **GPTM TimerB Prescale (GPTMTBPR)** register (see page 293).

10.2.2 32-Bit Timer Operating Modes

This section describes the three GPTM 32-bit timer modes (One-Shot, Periodic, and RTC) and their configuration.

The GPTM is placed into 32-bit mode by writing a 0 (One-Shot/Periodic 32-bit timer mode) or a 1 (RTC mode) to the **GPTM Configuration (GPTMCFG)** register. In both configurations, certain GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM TimerA Interval Load (GPTMTAILR)** register [15:0], see page 288
- **GPTM TimerB Interval Load (GPTMTBILR)** register [15:0], see page 289
- **GPTM TimerA (GPTMTAR)** register [15:0], see page 294
- **GPTM TimerB (GPTMTBR)** register [15:0], see page 295

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0]:GPTMTAILR[15:0]
```

Likewise, a read access to **GPTMTAR** returns the value:

```
GPTMTBR[15:0]:GPTMTAR[15:0]
```

10.2.2.1 32-Bit One-Shot/Periodic Timer Mode

In 32-bit one-shot and periodic timer modes, the concatenated versions of the TimerA and TimerB registers are configured as a 32-bit down-counter. The selection of one-shot or periodic mode is determined by the value written to the **TAMR** field of the **GPTM TimerA Mode (GPTMTAMR)** register (see page 275), and there is no need to write to the **GPTM TimerB Mode (GPTMTBMR)** register.

When software writes the **TAEN** bit in the **GPTM Control (GPTMCTL)** register (see page 279), the timer begins counting down from its preloaded value. Once the 0x0000.0000 state is reached, the timer reloads its start value from the concatenated **GPTMTAILR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the **TAEN** bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting.

In addition to reloading the count value, the GPTM generates interrupts and triggers when it reaches the 0x000.0000 state. The GPTM sets the **TATORIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 284), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 286). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTIMR)** register (see page 282), the GPTM also sets the **TATOMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 285). The trigger is enabled by setting the **TAOTE** bit in **GPTMCTL**, and can trigger SoC-level events such as ADC conversions.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the **TASTALL** bit in the **GPTMCTL** register is asserted, the timer freezes counting until the signal is deasserted.

10.2.2.2 32-Bit Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the TimerA and TimerB registers are configured as a 32-bit up-counter. When RTC mode is selected for the first time, the counter is loaded with a value of 0x0000.0001. All subsequent load values must be written to the **GPTM TimerA Match (GPTMTAMATCHR)** register (see page 290) by the controller.

The input clock on the **CCP0**, **CCP2**, or **CCP4** pins is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1 Hz rate and is passed along to the input of the 32-bit counter.

When software writes the **TAEN** bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x0000.0001. When the current count value matches the preloaded value in the **GPTMTAMATCHR** register, it rolls over to a value of 0x0000.0000 and continues counting until either a hardware reset, or it is disabled by software (clearing the **TAEN** bit). When a match occurs, the GPTM asserts the **RTCRES** bit in **GPTMRIS**. If the RTC interrupt is enabled in **GPTIMR**, the GPTM also sets the **RTCMIS** bit in **GPTMISR** and generates a controller interrupt. The status flags are cleared by writing the **RTCCINT** bit in **GPTMICR**.

If the **TASTALL** and/or **TBSTALL** bits in the **GPTMCTL** register are set, the timer does not freeze if the **RTCEN** bit is set in **GPTMCTL**.

10.2.3 16-Bit Timer Operating Modes

The GPTM is placed into global 16-bit mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 274). This section describes each of the GPTM 16-bit modes of operation. TimerA and TimerB have identical modes, so a single description is given using an *n* to reference both.

10.2.3.1 16-Bit One-Shot/Periodic Timer Mode

In 16-bit one-shot and periodic timer modes, the timer is configured as a 16-bit down-counter with an optional 8-bit prescaler that effectively extends the counting range of the timer to 24 bits. The selection of one-shot or periodic mode is determined by the value written to the **TnMR** field of the **GPTMTnMR** register. The optional prescaler is loaded into the **GPTM Timern Prescale (GPTMTnPR)** register.

When software writes the **TnEN** bit in the **GPTMCTL** register, the timer begins counting down from its preloaded value. Once the 0x0000 state is reached, the timer reloads its start value from **GPTMTnILR** and **GPTMTnPR** on the next cycle. If configured to be a one-shot timer, the timer stops counting and clears the **TnEN** bit in the **GPTMCTL** register. If configured as a periodic timer, it continues counting.

In addition to reloading the count value, the timer generates interrupts and triggers when it reaches the 0x0000 state. The GPTM sets the **TnTORIS** bit in the **GPTMRIS** register, and holds it until it is cleared by writing the **GPTMICR** register. If the time-out interrupt is enabled in **GPTIMR**, the GPTM also sets the **TnTOMIS** bit in **GPTMISR** and generates a controller interrupt. The trigger is enabled by setting the **TnOTE** bit in the **GPTMCTL** register, and can trigger SoC-level events such as ADC conversions.

If software reloads the **GPTMTAILR** register while the counter is running, the counter loads the new value on the next clock cycle and continues counting from the new value.

If the T_{nSTALL} bit in the **GPTMCTL** register is enabled, the timer freezes counting until the signal is deasserted.

The following example shows a variety of configurations for a 16-bit free running timer while using the prescaler. All values assume a 50-MHz clock with $T_c=20$ ns (clock period).

Table 10-2. 16-Bit Timer With Prescaler Configurations

Prescale	#Clock (T c) ^a	Max Time	Units
00000000	1	1.3107	mS
00000001	2	2.6214	mS
00000010	3	3.9321	mS
-----	--	--	--
11111100	254	332.9229	mS
11111110	255	334.2336	mS
11111111	256	335.5443	mS

a. T_c is the clock period.

10.2.3.2 16-Bit Input Edge Count Mode

Note: For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

Note: The prescaler is not available in 16-Bit Input Edge Count mode.

In Edge Count mode, the timer is configured as a down-counter capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge Count mode, the T_{nCMR} bit of the **GPTMTnMR** register must be set to 0. The type of edge that the timer counts is determined by the T_{nEVENT} fields of the **GPTMCTL** register. During initialization, the **GPTM Timern Match (GPTMTnMATCHR)** register is configured so that the difference between the value in the **GPTMTnILR** register and the **GPTMTnMATCHR** register equals the number of edge events that must be counted.

When software writes the T_{nEN} bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements the counter by 1 until the event count matches **GPTMTnMATCHR**. When the counts match, the GPTM asserts the C_{nMRIS} bit in the **GPTMRIS** register (and the C_{nMMIS} bit, if the interrupt is not masked). The counter is then reloaded using the value in **GPTMTnILR**, and stopped since the GPTM automatically clears the T_{nEN} bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until T_{nEN} is re-enabled by software.

Figure 10-2 on page 267 shows how input edge count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted since the timer automatically clears the T_{nEN} bit after the current count matches the value in the **GPTMTnMR** register.

Figure 10-2. 16-Bit Input Edge Count Mode Example

10.2.3.3 16-Bit Input Edge Time Mode

Note: For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

Note: The prescaler is not available in 16-Bit Input Edge Time mode.

In Edge Time mode, the timer is configured as a free-running down-counter initialized to the value loaded in the **GPTMTnILR** register (or 0xFFFF at reset). This mode allows for event capture of either rising or falling edges, but not both. The timer is placed into Edge Time mode by setting the **TnCMR** bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the **TnEVENT** fields of the **GPTMCnTL** register.

When software writes the **TnEN** bit in the **GPTMCTL** register, the timer is enabled for event capture. When the selected input event is detected, the current **Tn** counter value is captured in the **GPTMTnR** register and is available to be read by the controller. The GPTM then asserts the **CnERIS** bit (and the **CnEMIS** bit, if the interrupt is not masked).

After an event has been captured, the timer does not stop counting. It continues to count until the **TnEN** bit is cleared. When the timer reaches the 0x0000 state, it is reloaded with the value from the **GPTMnILR** register.

Figure 10-3 on page 268 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the **GPTMTnR** register, and is held there until another rising edge is detected (at which point the new count value is loaded into **GPTMTnR**).

Figure 10-3. 16-Bit Input Edge Time Mode Example

10.2.3.4 16-Bit PWM Mode

Note: The prescaler is not available in 16-Bit PWM mode.

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a down-counter with a start value (and thus period) defined by **GPTMTnILR**. PWM mode is enabled with the **GPTMTnMR** register by setting the T_nAMS bit to 0x1, the T_nCMR bit to 0x0, and the T_nMR field to 0x2.

When software writes the T_nEN bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0000 state. On the next counter cycle, the counter reloads its start value from **GPTMTnILR** and continues counting until disabled by software clearing the T_nEN bit in the **GPTMCTL** register. No interrupts or status bits are asserted in PWM mode.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** register (its start state), and is deasserted when the counter value equals the value in the **GPTM Timern Match Register (GPTMnMATCHR)**. Software has the capability of inverting the output PWM signal by setting the T_nPWML bit in the **GPTMCTL** register.

Figure 10-4 on page 269 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and $T_nPWML = 0$ (duty cycle would be 33% for the $T_nPWML = 1$ configuration). For this example, the start value is **GPTMnILR=0xC350** and the match value is **GPTMnMR=0x411A**.

Figure 10-4. 16-Bit PWM Mode Example

10.3 Initialization and Configuration

To use the general-purpose timers, the peripheral clock must be enabled by setting the `TIMER0`, `TIMER1`, `TIMER2`, and `TIMER3` bits in the `RCGC1` register.

This section shows module initialization and configuration examples for each of the supported timer modes.

10.3.1 32-Bit One-Shot/Periodic Timer Mode

The GPTM is configured for 32-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the `TAEN` bit in the `GPTMCTL` register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0.
3. Set the `TAMR` field in the **GPTM TimerA Mode Register (GPTMTAMR)**:
 - a. Write a value of 0x1 for One-Shot mode.
 - b. Write a value of 0x2 for Periodic mode.
4. Load the start value into the **GPTM TimerA Interval Load Register (GPTMTAILR)**.
5. If interrupts are required, set the `TATOIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
6. Set the `TAEN` bit in the `GPTMCTL` register to enable the timer and start counting.

7. Poll the `TATORIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `TATOCINT` bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

In One-Shot mode, the timer stops counting after step 7 on page 270. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

10.3.2 32-Bit Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on its `CCP0`, `CCP2`, or `CCP4` pins. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the `TAEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x1.
3. Write the desired match value to the **GPTM TimerA Match Register (GPTMTAMATCHR)**.
4. Set/clear the `RTCEN` bit in the **GPTM Control Register (GPTMCTL)** as desired.
5. If interrupts are required, set the `RTCIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
6. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTAMATCHR** register, the counter is re-loaded with 0x0000.0000 and begins counting. If an interrupt is enabled, it does not have to be cleared.

10.3.3 16-Bit One-Shot/Periodic Timer Mode

A timer is configured for 16-bit One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x4.
3. Set the `TnMR` field in the **GPTM Timer Mode (GPTMTnMR)** register:
 - a. Write a value of 0x1 for One-Shot mode.
 - b. Write a value of 0x2 for Periodic mode.
4. If a prescaler is to be used, write the prescale value to the **GPTM Timern Prescale Register (GPTMTnPR)**.
5. Load the start value into the **GPTM Timer Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the `TnTOIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the `TnEN` bit in the **GPTM Control Register (GPTMCTL)** to enable the timer and start counting.
8. Poll the `TnTORIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `TnTOCINT` bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

In One-Shot mode, the timer stops counting after step 8 on page 270. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode does not stop counting after it times out.

10.3.4 16-Bit Input Edge Count Mode

A timer is configured to Input Edge Count mode by the following sequence:

1. Ensure the timer is disabled (the $TnEN$ bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the $TnCMR$ field to 0x0 and the $TnMR$ field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the $TnEVENT$ field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timern Interval Load (GPTMTnILR)** register.
6. Load the desired event count into the **GPTM Timern Match (GPTMTnMATCHR)** register.
7. If interrupts are required, set the $CnMIM$ bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the $TnEN$ bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
9. Poll the $CnMRIS$ bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the $CnMCINT$ bit of the **GPTM Interrupt Clear (GPTMICR)** register.

In Input Edge Count Mode, the timer stops after the desired number of edge events has been detected. To re-enable the timer, ensure that the $TnEN$ bit is cleared and repeat step 4 on page 271 through step 9 on page 271.

10.3.5 16-Bit Input Edge Timing Mode

A timer is configured to Input Edge Timing mode by the following sequence:

1. Ensure the timer is disabled (the $TnEN$ bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the $TnCMR$ field to 0x1 and the $TnMR$ field to 0x3.
4. Configure the type of event that the timer captures by writing the $TnEVENT$ field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timern Interval Load (GPTMTnILR)** register.
6. If interrupts are required, set the $CnEIM$ bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
7. Set the $TnEN$ bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
8. Poll the $CnERIS$ bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the $CnECINT$ bit of the **GPTM**

Interrupt Clear (GPTMICR) register. The time at which the event happened can be obtained by reading the **GPTM Timern (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register. The change takes effect at the next cycle after the write.

10.3.6 16-Bit PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the $TnEN$ bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x4.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the $TnAMS$ bit to 0x1, the $TnCMR$ bit to 0x0, and the $TnMR$ field to 0x2.
4. Configure the output state of the PWM signal (whether or not it is inverted) in the $TnEVENT$ field of the **GPTM Control (GPTMCTL)** register.
5. Load the timer start value into the **GPTM Timern Interval Load (GPTMTnILR)** register.
6. Load the **GPTM Timern Match (GPTMTnMATCHR)** register with the desired value.
7. Set the $TnEN$ bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Timing mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

10.4 Register Map

Table 10-3 on page 272 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- Timer0: 0x4003.0000
- Timer1: 0x4003.1000
- Timer2: 0x4003.2000
- Timer3: 0x4003.3000

Table 10-3. Timers Register Map

Offset	Name	Type	Reset	Description	See page
0x000	GPTMCFG	R/W	0x0000.0000	GPTM Configuration	274
0x004	GPTMTAMR	R/W	0x0000.0000	GPTM TimerA Mode	275
0x008	GPTMTBMR	R/W	0x0000.0000	GPTM TimerB Mode	277
0x00C	GPTMCTL	R/W	0x0000.0000	GPTM Control	279

Offset	Name	Type	Reset	Description	See page
0x018	GPTMIMR	R/W	0x0000.0000	GPTM Interrupt Mask	282
0x01C	GPTMRIS	RO	0x0000.0000	GPTM Raw Interrupt Status	284
0x020	GPTMMIS	RO	0x0000.0000	GPTM Masked Interrupt Status	285
0x024	GPTMICR	W1C	0x0000.0000	GPTM Interrupt Clear	286

0x02C	GPTMTBILR	R/W	0x0000.FFFF	GPTM TimerB Interval Load	289
0x030	GPTMTAMATCHR	R/W	0x0000.FFFF (16-bit mode) 0xFFFF.FFFF (32-bit mode)	GPTM TimerA Match	290
0x034	GPTMTBMATCHR	R/W	0x0000.FFFF	GPTM TimerB Match	291
0x038	GPTMTAPR	R/W	0x0000.0000	GPTM TimerA Prescale	292
0x03C	GPTMTBPR	R/W	0x0000.0000	GPTM TimerB Prescale	293
0x048	GPTMTAR	RO	0x0000.FFFF (16-bit mode) 0xFFFF.FFFF (32-bit mode)	GPTM TimerA	294
0x04C	GPTMTBR	RO	0x0000.FFFF	GPTM TimerB	295

10.5 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

Register 1: GPTM Configuration (GPTMCFG), offset 0x000

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

GPTM Configuration (GPTMCFG)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x000
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	GPTMCFG	R/W	0x0	GPTM Configuration

The GPTMCFG values are defined as follows:

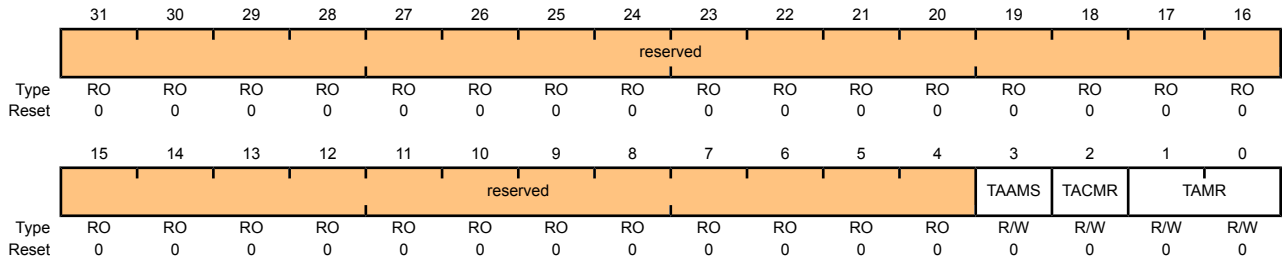

Value	Description
0x0	32-bit timer configuration.
0x1	32-bit real-time clock (RTC) counter configuration.
0x2	Reserved
0x3	Reserved
0x4-0x7	16-bit timer configuration, function is controlled by bits 1:0 of GPTMTAMR and GPTMTBMR.

Register 2: GPTM TimerA Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the **TAAMS** bit to 0x1, the **TACMR** bit to 0x0, and the **TAMR** field to 0x2.

GPTM TimerA Mode (GPTMTAMR)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x004
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
3	TAAMS	R/W	0	GPTM TimerA Alternate Mode Select The TAAMS values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Capture mode is enabled.</td> </tr> <tr> <td>1</td> <td>PWM mode is enabled.</td> </tr> </tbody> </table> <p>Note: To enable PWM mode, you must also clear the TACMR bit and set the TAMR field to 0x2.</p>	Value	Description	0	Capture mode is enabled.	1	PWM mode is enabled.
Value	Description									
0	Capture mode is enabled.									
1	PWM mode is enabled.									
2	TACMR	R/W	0	GPTM TimerA Capture Mode The TACMR values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Edge-Count mode</td> </tr> <tr> <td>1</td> <td>Edge-Time mode</td> </tr> </tbody> </table>	Value	Description	0	Edge-Count mode	1	Edge-Time mode

Value	Description													
0x0	Reserved													
0x1	One-Shot Timer mode													
0x2	Periodic Timer mode													
0x3	Capture mode													

Register 3: GPTM TimerB Mode (GPTMTBMR), offset 0x008

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in 16-bit PWM mode, set the **TBAMS** bit to 0x1, the **TBCMR** bit to 0x0, and the **TBMR** field to 0x2.

GPTM TimerB Mode (GPTMTBMR)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x008

Value	Description													
0x0	Reserved													
0x1	One-Shot Timer mode													
0x2	Periodic Timer mode													
0x3	Capture mode													

Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

GPTM Control (GPTMCTL)

Timer0 base: 0x4003.0000

Value	Description									
0	Interrupt is disabled.									
1	Interrupt is enabled.									

Register 6: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

GPTM Raw Interrupt Status (GPTMRIS)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x01C
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:11	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
10	CBERIS	RO	0	GPTM CaptureB Event Raw Interrupt This is the CaptureB Event interrupt status prior to masking.
9	CBMRIS	RO	0	GPTM CaptureB Match Raw Interrupt This is the CaptureB Match interrupt status prior to masking.
8	TBTORIS	RO	0	GPTM TimerB Time-Out Raw Interrupt This is the TimerB time-out interrupt status prior to masking.
7:4	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	RTCRIS	RO	0	GPTM RTC Raw Interrupt This is the RTC Event interrupt status prior to masking.
2	CAERIS	RO	0	GPTM CaptureA Event Raw Interrupt This is the CaptureA Event interrupt status prior to masking.
1	CAMRIS	RO	0	GPTM CaptureA Match Raw Interrupt This is the CaptureA Match interrupt status prior to masking.
0	TATORIS	RO	0	GPTM TimerA Time-Out Raw Interrupt This the TimerA time-out interrupt status prior to masking.

Register 7: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

GPTM Masked Interrupt Status (GPTMMIS)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x020

Value	Description									
0	The interrupt is unaffected.									
1	The interrupt is cleared.									

Register 9: GPTM TimerA Interval Load (GPTMTAILR), offset 0x028

This register is used to load the starting count value into the timer. When GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM TimerB Interval Load (GPTMTBILR)** register). In 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

GPTM TimerA Interval Load (GPTMTAILR)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x028

Type R/W, reset 0x0000.FFFF (16-bit mode) and 0xFFFF.FFFF (32-bit mode)

Bit/Field	Name	Type	Reset	Description
31:16	TAILRH	R/W	0xFFFF (32-bit mode) 0x0000 (16-bit mode)	GPTM TimerA Interval Load Register High When configured for 32-bit mode via the GPTMCFG register, the GPTM TimerB Interval Load (GPTMTBILR) register loads this value on a write. A read returns the current value of GPTMTBILR . In 16-bit mode, this field reads as 0 and does not have an effect on the state of GPTMTBILR .
15:0	TAILRL	R/W	0xFFFF	GPTM TimerA Interval Load Register Low For both 16- and 32-bit modes, writing this field loads the counter for TimerA. A read returns the current value of GPTMTAILR .

Register 10: GPTM TimerB Interval Load (GPTMTBILR), offset 0x02C

This register is used to load the starting count value into TimerB. When the GPTM is configured to a 32-bit mode, **GPTMTBILR** returns the current value of TimerB and ignores writes.

GPTM TimerB Interval Load (GPTMTBILR)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x02C
 Type R/W, reset 0x0000.FFFF

31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TBILRL	R/W	0xFFFF	GPTM TimerB Interval Load Register

When the GPTM is not configured as a 32-bit timer, a write to this field updates **GPTMTBILR**. In 32-bit mode, writes are ignored, and reads return the current value of **GPTMTBILR**.

Register 11: GPTM TimerA Match (GPTMTAMATCHR), offset 0x030

This register is used in 32-bit Real-Time Clock mode and 16-bit PWM and Input Edge Count modes.

GPTM TimerA Match (GPTMTAMATCHR)

Timer0 base: 0x4003.0000

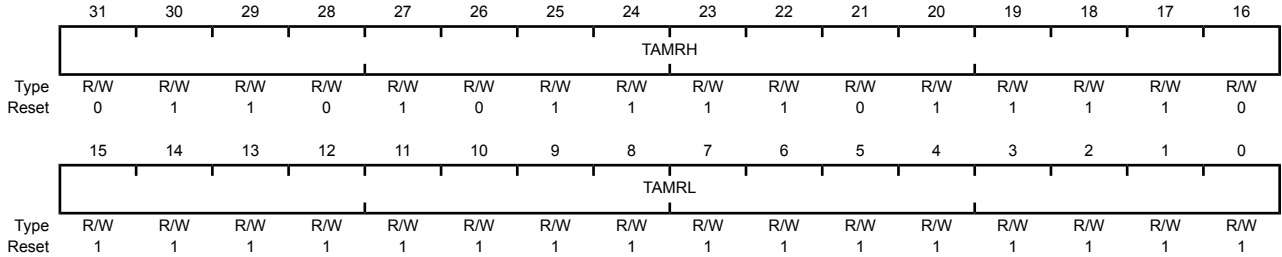

Timer1 base: 0x4003.1000

Timer2 base: 0x4003.2000

Timer3 base: 0x4003.3000

Offset 0x030

Type R/W, reset 0x0000.FFFF (16-bit mode) and 0xFFFF.FFFF (32-bit mode)

Bit/Field	Name	Type	Reset	Description
31:16	TAMRH	R/W	0xFFFF (32-bit mode) 0x0000 (16-bit mode)	GPTM TimerA Match Register High When configured for 32-bit Real-Time Clock (RTC) mode via the GPTMCFG register, this value is compared to the upper half of GPTMTAR , to determine match events. In 16-bit mode, this field reads as 0 and does not have an effect on the state of GPTMTBMATCHR .
15:0	TAMRL	R/W	0xFFFF	GPTM TimerA Match Register Low When configured for 32-bit Real-Time Clock (RTC) mode via the GPTMCFG register, this value is compared to the lower half of GPTMTAR , to determine match events. When configured for PWM mode, this value along with GPTMTAILR , determines the duty cycle of the output PWM signal. When configured for Edge Count mode, this value along with GPTMTAILR , determines how many edge events are counted. The total number of edge events counted is equal to the value in GPTMTAILR minus this value.

Register 12: GPTM TimerB Match (GPTMTBMATCHR), offset 0x034

This register is used in 16-bit PWM and Input Edge Count modes.

GPTM TimerB Match (GPTMTBMATCHR)

Timer0 base: 0x4003.0000
 Timer1 base: 0x4003.1000
 Timer2 base: 0x4003.2000
 Timer3 base: 0x4003.3000
 Offset 0x034
 Type R/W, reset 0x0000.FFFF

A read returns the current value of the **GPTM TimerB Count Register**, except in Input Edge Count mode, when it returns the timestamp from the last edge event.

11 Watchdog Timer

A watchdog timer can generate nonmaskable interrupts (NMIs) or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way.

The Stellaris® Watchdog Timer module consists of a 32-bit down counter, a programmable load register, interrupt generation logic, a locking register, and user-enabled stalling.

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

11.1 Block Diagram

Figure 11-1. WDT Module Block Diagram

11.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the

Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled (via the `WatchdogResetEnable` function), the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

11.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the `WDT` bit in the **RCGC0** register. The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If the Watchdog is configured to trigger system resets, set the `RESEN` bit in the **WDTCTL** register.
3. Set the `INTEN` bit in the **WDTCTL** register to enable the Watchdog and lock the control register.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of `0x1ACC.E551`.

11.4 Register Map

Table 11-1 on page 297 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address of `0x4000.0000`.

11.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

Watchdog Load (WDTLOAD)

Base 0x4000.0000

Offset 0x000

Type R/W, reset 0xFFFF.FFFF

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	WDTLoad

Bit/Field	Name	Type	Reset	Description
31:0	WDTLoad	R/W	0xFFFF.FFFF	Watchdog Load Value

Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

Watchdog Value (WDTVALUE)

Base 0x4000.0000

Offset 0x004

Type RO, reset 0xFFFF.FFFF

Bit/Field	Name	Type	Reset	Description
31:0	WDTValue	RO	0xFFFF.FFFF	Watchdog Value Current value of the 32-bit down counter.

Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled, all subsequent writes to the control register are ignored. The only mechanism that can re-enable writes is a hardware reset.

Watchdog Control (WDTCTL)

Base 0x4000.0000
Offset 0x008
Type R/W, reset 0x0000.0000

1	Enable the Watchdog module reset output.									
0	INTEN	R/W	0	Watchdog Interrupt Enable The INTEN values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset).</td> </tr> <tr> <td>1</td> <td>Interrupt event enabled. Once enabled, all writes are ignored.</td> </tr> </tbody> </table>	Value	Description	0	Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset).	1	Interrupt event enabled. Once enabled, all writes are ignored.
Value	Description									
0	Interrupt event disabled (once this bit is set, it can only be cleared by a hardware reset).									
1	Interrupt event enabled. Once enabled, all writes are ignored.									

Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Value for a read or reset is indeterminate.

Watchdog Interrupt Clear (WDTICR)

Base 0x4000.0000

Offset 0x00C

Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:0	WDTIntClr	WO	-	Watchdog Interrupt Clear

Register 5: Watchdog Raw Interrupt Status (WDTRIS), offset 0x010

This register is the raw interrupt status register. Watchdog interrupt events can be monitored via this register if the controller interrupt is masked.

Watchdog Raw Interrupt Status (WDTRIS)

Base 0x4000.0000

Offset 0x010

Type RO, reset 0x0000.0000

8	STALL	R/W	0	<p>Watchdog Stall Enable</p> <p>When set to 1, if the Stellaris[®] microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting.</p>
7:0	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

Watchdog Lock (WDTLOCK)

Base 0x4000.0000
 Offset 0xC00
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
-----------	------	------	-------	-------------

31:0	WDTLock	R/W	0x0000	Watchdog Lock
------	---------	-----	--------	---------------

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates.

A read of this register returns the following values:

Value	Description
0x0000.0001	Locked
0x0000.0000	Unlocked

Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

Watchdog Peripheral Identification 4 (WDTPeriphID4)

12 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number.

The Stellaris[®] ADC module features 10-bit conversion resolution and supports four input channels, plus an internal temperature sensor. The ADC module contains a programmable sequencer which allows for the sampling of multiple analog input sources without controller intervention. Each sample sequence provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequence priority.

The Stellaris[®] ADC provides the following features:

- Four analog input channels
- Single-ended and differential-input configurations
- Internal temperature sensor
- Sample rate of 500 thousand samples/second
- Four programmable sample conversion sequences from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
 - Controller (software)
 - Timers
 - Analog Comparators
 - PWM
 - GPIO
- Hardware averaging of up to 64 samples for improved accuracy
- An internal 3-V reference is used by the converter.
- Power and ground for the analog circuitry is separate from the digital power and ground.

12.1 Block Diagram

Figure 12-1. ADC Module Block Diagram

12.2 Functional Description

The Stellaris[®] ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approach found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the controller. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence.

12.2.1 Sample Sequencers

The sampling control and data capture is handled by the Sample Sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 12-1 on page 320 shows the maximum number of samples that each Sequencer can capture and its corresponding FIFO depth. In this implementation, each FIFO entry is a 32-bit word, with the lower 10 bits containing the conversion result.

Table 12-1. Samples and FIFO Depth of Sequencers

Sequencer	Number of Samples	Depth of FIFO
SS3	1	1
SS2	4	4
SS1	4	4
SS0	8	8

For a given sample sequence, each sample is defined by two 4-bit nibbles in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** nibbles select the input pin, while the **ADCSSCTLn** nibbles contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample Sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register, but can be configured before being enabled.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence is allowed. In the **ADCSSCTLn** register, the **Interrupt Enable (IE)** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTATn)** registers along with **FULL** and **EMPTY** status flags. Overflow and underflow conditions are monitored using the **ADCSTAT** and **ADCUSTAT** registers.

12.2.2 Module Control

Outside of the Sample Sequencers, the remainder of the control logic is responsible for tasks such as interrupt generation, sequence prioritization, and trigger configuration.

Most of the ADC control logic runs at the ADC clock rate of 14-18 MHz. The internal ADC divider is configured automatically by hardware when the system **XTAL** is selected. The automatic clock divider configuration targets 16.667 MHz operation for all Stellaris® devices.

12.2.2.1 Interrupts

The Sample Sequencers dictate the events that cause interrupts, but they don't have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signal is controlled by the state of the **MASK** bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of a Sample Sequencer's interrupt signal, and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows the logical AND of the **ADCRIS** register's **INR** bit and the **ADCIM** register's **MASK** bits. Interrupts are cleared by writing a 1 to the corresponding **IN** bit in **ADCISC**.

12.2.2.2 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active Sample Sequencer units with the same priority do not provide consistent results, so software must ensure that all active Sample Sequencer units have a unique priority value.

12.2.2.3 Sampling Events

Sample triggering for each Sample Sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. The external peripheral triggering sources vary by Stellaris® family member,

but all devices share the "Controller" and "Always" triggers. Software can initiate sampling by setting the `CH` bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

When using the "Always" trigger, care must be taken. If a sequence's priority is too high, it is possible to starve other lower priority sequences.

12.2.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 338). There is a single averaging circuit and all input channels receive the same amount of averaging whether they are single-ended or differential.

12.2.4 Analog-to-Digital Converter

The converter itself generates a 10-bit output value for selected analog input. Special analog pads are used to minimize the distortion on the input. An internal 3 V reference is used by the converter resulting in sample values ranging from 0x000 at 0 V input to 0x3FF at 3 V input when in single-ended input mode.

12.2.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the `D` bit (in the **ADCSSCTL0** register) in a step's configuration nibble.

When a sequence step is configured for differential sampling, its corresponding value in the **ADCSSMUX** register must be set to one of the four differential pairs, numbered 0-3. Differential pair 0 samples analog inputs 0 and 1; differential pair 1 samples analog inputs 2 and 3; and so on (see Table 12-2 on page 322). The ADC does not support other differential pairings such as analog input 0 with analog input 3. The number of differential pairs supported is dependent on the number of analog inputs (see Table 12-2 on page 322).

Table 12-2. Differential Sampling Pairs

Differential Pair	Analog Inputs
0	0 and 1
1	2 and 3

The voltage sampled in differential mode is the difference between the odd and even channels:

ΔV (differential voltage) = V_{IN_EVEN} (even channels) – V_{IN_ODD} (odd channels), therefore:

- If $\Delta V = 0$, then the conversion result = 0x1FF
- If $\Delta V > 0$, then the conversion result > 0x1FF (range is 0x1FF–0x3FF)
- If $\Delta V < 0$, then the conversion result < 0x1FF (range is 0–0x1FF)

The differential pairs assign polarities to the analog inputs: the even-numbered input is always positive, and the odd-numbered input is always negative. In order for a valid conversion result to

appear, the negative input must be in the range of ± 1.5 V of the positive input. If an analog input is greater than 3 V or less than 0 V (the valid range for analog inputs), the input voltage is clipped, meaning it appears as either 3 V or 0 V, respectively, to the ADC.

Figure 12-2 on page 323 shows an example of the negative input centered at 1.5 V. In this configuration, the differential range spans from -1.5 V to 1.5 V. Figure 12-3 on page 323 shows an example where the negative input is centered at -0.75 V, meaning inputs on the positive input saturate past a differential voltage of -0.75 V since the input voltage is less than 0 V. Figure 12-4 on page 324 shows an example of the negative input centered at 2.25 V, where inputs on the positive channel saturate past a differential voltage of 0.75 V since the input voltage would be greater than 3 V.

Figure 12-2. Differential Sampling Range, $V_{IN_ODD} = 1.5$ V

Figure 12-3. Differential Sampling Range, $V_{IN_ODD} = 0.75$ V

Figure 12-4. Differential Sampling Range, $V_{IN_ODD} = 2.25\text{ V}$

12.2.6 Internal Temperature Sensor

The internal temperature sensor provides an analog temperature reading as well as a reference voltage. The voltage at the output terminal SENS0 is given by the following equation:

$$SENS0 = 2.7 - ((T + 55) / 75)$$

This relation is shown in Figure 12-5 on page 324.

Figure 12-5. Internal Temperature Sensor Characteristic

12.3 Initialization and Configuration

In order for the ADC module to be used, the PLL must be enabled and using a supported crystal frequency (see the **RCC** register). Using unsupported frequencies can cause faulty operation in the ADC module.

12.3.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps. The main steps include enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the Sample Sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock by writing a value of 0x0001.0000 to the **RCGC1** register (see page 111).
2. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 249) in the associated GPIO block.
3. If required by the application, reconfigure the Sample Sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority, and Sample Sequencer 3 as the lowest priority.

12.3.2 Sample Sequencer Configuration

Configuration of the Sample Sequencers is slightly more complex than the module initialization since each sample sequence is completely programmable.

The configuration for each Sample Sequencer should be as follows:

1. Ensure that the Sample Sequencer is disabled by writing a 0 to the corresponding **ASEN** bit in the **ADCACTSS** register. Programming of the Sample Sequencers is allowed without having them enabled. Disabling the Sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the Sample Sequencer in the **ADCEMUX** register.
3. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUXn** register.
4. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTLn** register. When programming the last nibble, ensure that the **END** bit is set. Failure to set the **END** bit causes unpredictable behavior.
5. If interrupts are to be used, write a 1 to the corresponding **MASK** bit in the **ADCIM** register.
6. Enable the Sample Sequencer logic by writing a 1 to the corresponding **ASEN** bit in the **ADCACTSS** register.

12.4 Register Map

Table 12-3 on page 325 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to the ADC base address of 0x4003.8000.

Table 12-3. ADC Register Map

12.5 Register Descriptions

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000

This register controls the activation of the Sample Sequencers. Each Sample Sequencer can be enabled/disabled independently.

ADC Active Sample Sequencer (ADCACTSS)

Base 0x4003.8000

Offset 0x000

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ASEN3	R/W	0	<p>ADC SS3 Enable</p> <p>Specifies whether Sample Sequencer 3 is enabled. If set, the sample sequence logic for Sequencer 3 is active. Otherwise, the Sequencer is inactive.</p>
2	ASEN2	R/W	0	<p>ADC SS2 Enable</p> <p>Specifies whether Sample Sequencer 2 is enabled. If set, the sample sequence logic for Sequencer 2 is active. Otherwise, the Sequencer is inactive.</p>
1	ASEN1	R/W	0	<p>ADC SS1 Enable</p> <p>Specifies whether Sample Sequencer 1 is enabled. If set, the sample sequence logic for Sequencer 1 is active. Otherwise, the Sequencer is inactive.</p>
0	ASEN0	R/W	0	<p>ADC SS0 Enable</p> <p>Specifies whether Sample Sequencer 0 is enabled. If set, the sample sequence logic for Sequencer 0 is active. Otherwise, the Sequencer is inactive.</p>

Register 2: ADC Raw Interrupt Status (ADCRIS), offset 0x004

This register shows the status of the raw interrupt signal of each Sample Sequencer. These bits may be polled by software to look for interrupt conditions without having to generate controller interrupts.

ADC Raw Interrupt Status (ADCRIS)

Base 0x4003.8000
 Offset 0x004
 Type RO, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	INR3	RO	0	SS3 Raw Interrupt Status Set by hardware when a sample with its respective ADCSSCTL3 <small>IE</small> bit has completed conversion. This bit is cleared by writing a 1 to the ADCISC <small>IN3</small> bit.
2	INR2	RO	0	SS2 Raw Interrupt Status Set by hardware when a sample with its respective ADCSSCTL2 <small>IE</small> bit has completed conversion. This bit is cleared by writing a 1 to the ADCISC <small>IN2</small> bit.
1	INR1	RO	0	SS1 Raw Interrupt Status Set by hardware when a sample with its respective ADCSSCTL1 <small>IE</small> bit has completed conversion. This bit is cleared by writing a 1 to the ADCISC <small>IN1</small> bit.
0	INR0	RO	0	SS0 Raw Interrupt Status Set by hardware when a sample with its respective ADCSSCTL0 <small>IE</small> bit has completed conversion. This bit is cleared by writing a 1 to the ADCISC <small>IN0</small> bit.

Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the Sample Sequencer raw interrupt signals are promoted to controller interrupts. The raw interrupt signal for each Sample Sequencer can be masked independently.

ADC Interrupt Mask (ADCIM)

Base 0x4003.8000
Offset 0x008
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved												MASK3	MASK2	MASK1	MASK0
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	MASK3	R/W	0	SS3 Interrupt Mask Specifies whether the raw interrupt signal from Sample Sequencer 3 (ADCRIS register INR3 bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.
2	MASK2	R/W	0	SS2 Interrupt Mask Specifies whether the raw interrupt signal from Sample Sequencer 2 (ADCRIS register INR2 bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.
1	MASK1	R/W	0	SS1 Interrupt Mask Specifies whether the raw interrupt signal from Sample Sequencer 1 (ADCRIS register INR1 bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.
0	MASK0	R/W	0	SS0 Interrupt Mask Specifies whether the raw interrupt signal from Sample Sequencer 0 (ADCRIS register INR0 bit) is promoted to a controller interrupt. If set, the raw interrupt signal is promoted to a controller interrupt. Otherwise, it is not.

Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing interrupt conditions, and shows the status of controller interrupts generated by the Sample Sequencers. When read, each bit field is the logical AND of the respective *INR* and *MASK* bits. Interrupts are cleared by writing a 1 to the corresponding bit position. If software is polling the **ADCRIS** instead of generating interrupts, the *INR* bits are still cleared via the **ADCISC** register, even if the *IN* bit is not set.

ADC Interrupt Status and Clear (ADCISC)

Base 0x4003.8000
 Offset 0x00C
 Type R/W1C, reset 0x0000.0000

Register 8: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020

This register sets the priority for each of the Sample Sequencers. Out of reset, Sequencer 0 has the highest priority, and sample sequence 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority or the ADC behavior is inconsistent.

ADC Sample Sequencer Priority (ADCSSPRI)

Base 0x4003.8000
 Offset 0x020
 Type R/W, reset 0x0000.3210

Bit/Field	Name	Type	Reset	Description
31:14	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
13:12	SS3	R/W	0x3	SS3 Priority The SS3 field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 3. A priority encoding of 0 is highest and 3 is lowest. The priorities assigned to the Sequencers must be uniquely mapped. ADC behavior is not consistent if two or more fields are equal.
11:10	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:8	SS2	R/W	0x2	SS2 Priority The SS2 field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 2.
7:6	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:4	SS1	R/W	0x1	SS1 Priority The SS1 field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 1.
3:2	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1:0	SS0	R/W	0x0	SS0 Priority The SS0 field contains a binary-encoded value that specifies the priority encoding of Sample Sequencer 0.

Register 9: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028

This register provides a mechanism for application software to initiate sampling in the Sample Sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

ADC Processor Sample Sequence Initiate (ADCPSSI)

Base 0x4003.8000
 Offset 0x028
 Type WO, reset -

Bit/Field	Name	Type	Reset	Description
31:4	reserved	WO	-	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SS3	WO	-	SS3 Initiate Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 3, assuming the Sequencer is enabled in the ADCACTSS register.
2	SS2	WO	-	SS2 Initiate Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 2, assuming the Sequencer is enabled in the ADCACTSS register.
1	SS1	WO	-	SS1 Initiate Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 1, assuming the Sequencer is enabled in the ADCACTSS register.
0	SS0	WO	-	SS0 Initiate Only a write by software is valid; a read of the register returns no meaningful data. When set by software, sampling is triggered on Sample Sequencer 0, assuming the Sequencer is enabled in the ADCACTSS register.

Register 10: ADC Sample Averaging Control (ADCSAC), offset 0x030

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from 2^{AVG} consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG = 7 provides unpredictable results.

ADC Sample Averaging Control (ADCSAC)

Base 0x4003.8000
 Offset 0x030
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:3	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2:0	AVG	R/W	0x0	Hardware Averaging Control Specifies the amount of hardware averaging that will be applied to ADC samples. The AVG field can be any value between 0 and 6. Entering a value of 7 creates unpredictable results.

Value	Description
0x0	No hardware oversampling
0x1	2x hardware oversampling
0x2	4x hardware oversampling
0x3	8x hardware oversampling
0x4	16x hardware oversampling
0x5	32x hardware oversampling
0x6	64x hardware oversampling
0x7	Reserved

Register 11: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0.

This register is 32-bits wide and contains information for eight possible samples.

ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

Base 0x4003.8000
Offset 0x040

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31	TS7	R/W	0	<p>8th Sample Temp Sensor Select</p> <p>The <code>TS7</code> bit is used during the eighth sample of the sample sequence and specifies the input source of the sample. If set, the temperature sensor is read. Otherwise, the input pin specified by the <code>ADCSSMUX</code> register is read.</p>
30	IE7	R/W	0	<p>8th Sample Interrupt Enable</p> <p>The <code>IE7</code> bit is used during the eighth sample of the sample sequence and specifies whether the raw interrupt signal (<code>INR0</code> bit) is asserted at the end of the sample's conversion. If the <code>MASK0</code> bit in the <code>ADCIM</code> register is set, the interrupt is promoted to a controller-level interrupt. When this bit is set, the raw interrupt is asserted, otherwise it is not. It is legal to have multiple samples within a sequence generate interrupts.</p>
29	END7	R/W	0	<p>8th Sample is End of Sequence</p> <p>The <code>END7</code> bit indicates that this is the last sample of the sequence. It is possible to end the sequence on any sample position. Samples defined after the sample containing a set <code>END</code> are not requested for conversion even though the fields may be non-zero. It is required that software write the <code>END</code> bit somewhere within the sequence. (Sample Sequencer 3, which only has a single sample in the sequence, is hardwired to have the <code>END0</code> bit set.)</p> <p>Setting this bit indicates that this sample is the last in the sequence.</p>
28	D7	R/W	0	<p>8th Sample Diff Input Select</p> <p>The <code>D7</code> bit indicates that the analog input is to be differentially sampled. The corresponding <code>ADCSSMUXx</code> nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1". The temperature sensor does not have a differential option. When set, the analog inputs are differentially sampled.</p>
27	TS6	R/W	0	<p>7th Sample Temp Sensor Select</p> <p>Same definition as <code>TS7</code> but used during the seventh sample.</p>

Bit/Field	Name	Type	Reset	Description
26	IE6	R/W	0	7th Sample Interrupt Enable Same definition as IE7 but used during the seventh sample.
25	END6	R/W	0	7th Sample is End of Sequence Same definition as END7 but used during the seventh sample.
24	D6	R/W	0	7th Sample Diff Input Select Same definition as D7 but used during the seventh sample.
23	TS5	R/W	0	6th Sample Temp Sensor Select Same definition as TS7 but used during the sixth sample.
22	IE5	R/W	0	6th Sample Interrupt Enable Same definition as IE7 but used during the sixth sample.
21	END5	R/W	0	6th Sample is End of Sequence Same definition as END7 but used during the sixth sample.
20	D5	R/W	0	6th Sample Diff Input Select Same definition as D7 but used during the sixth sample.
19	TS4	R/W	0	5th Sample Temp Sensor Select Same definition as TS7 but used during the fifth sample.
18	IE4	R/W	0	5th Sample Interrupt Enable Same definition as IE7 but used during the fifth sample.
17	END4	R/W	0	5th Sample is End of Sequence Same definition as END7 but used during the fifth sample.
16	D4	R/W	0	5th Sample Diff Input Select Same definition as D7 but used during the fifth sample.
15	TS3	R/W	0	4th Sample Temp Sensor Select Same definition as TS7 but used during the fourth sample.
14	IE3	R/W	0	4th Sample Interrupt Enable Same definition as IE7 but used during the fourth sample.

12	D3	R/W	0	4th Sample Diff Input Select Same definition as D7 but used during the fourth sample.
11	TS2	R/W	0	3rd Sample Temp Sensor Select Same definition as TS7 but used during the third sample.

Bit/Field	Name	Type	Reset	Description
10	IE2	R/W	0	3rd Sample Interrupt Enable Same definition as IE7 but used during the third sample.
9	END2	R/W	0	3rd Sample is End of Sequence Same definition as END7 but used during the third sample.
8	D2	R/W	0	3rd Sample Diff Input Select Same definition as D7 but used during the third sample.
7	TS1	R/W	0	2nd Sample Temp Sensor Select Same definition as TS7 but used during the second sample.
6	IE1	R/W	0	2nd Sample Interrupt Enable Same definition as IE7 but used during the second sample.
5	END1	R/W	0	2nd Sample is End of Sequence Same definition as END7 but used during the second sample.
4	D1	R/W	0	2nd Sample Diff Input Select Same definition as D7 but used during the second sample.
3	TS0	R/W	0	1st Sample Temp Sensor Select Same definition as TS7 but used during the first sample.
2	IE0	R/W	0	1st Sample Interrupt Enable Same definition as IE7 but used during the first sample.
1	END0	R/W	0	1st Sample is End of Sequence Same definition as END7 but used during the first sample. Since this sequencer has only one entry, this bit must be set.
0	D0	R/W	0	1st Sample Diff Input Select Same definition as D7 but used during the first sample.

Register 13: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048

Register 14: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068

Register 15: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088

Register 16: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8

This register contains the conversion results for samples collected with the Sample Sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0)

Base 0x4003.8000
 Offset 0x048
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9:0	DATA	RO	0x00	Conversion Result Data

Register 17: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C

Register 18: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C

Register 19: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C

Register 20: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC

This register provides a window into the Sample Sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO. The **ADCSSFSTAT0** register provides status on FIFO0, **ADCSSFSTAT1** on FIFO1, **ADCSSFSTAT2** on FIFO2, and **ADCSSFSTAT3** on FIFO3.

ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0)

13 Universal Asynchronous Receivers/Transmitters (UARTs)

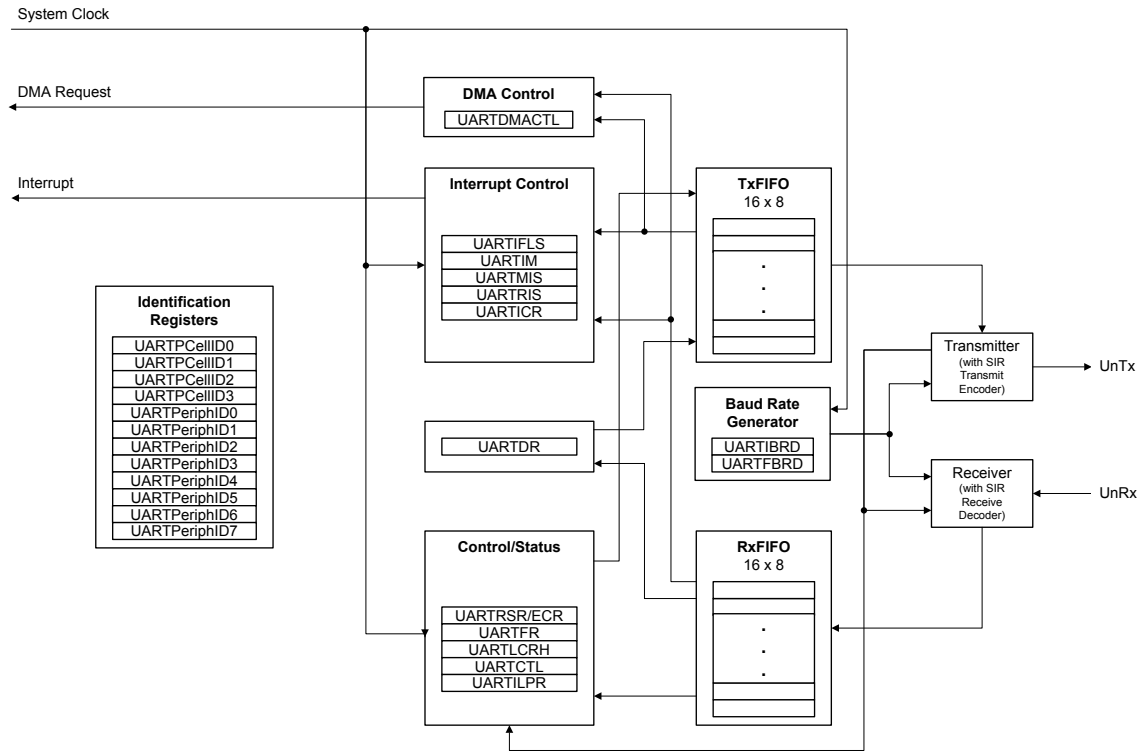

The Stellaris[®] Universal Asynchronous Receiver/Transmitter (UART) provides fully programmable, 16C550-type serial interface characteristics. The LM3S2671 controller is equipped with one UART module.

The UART has the following features:

- Separate transmit and receive FIFOs
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Programmable baud-rate generator allowing rates up to 3.125 Mbps
- Standard asynchronous communication bits for start, stop, and parity
- False start bit detection
- Line-break generation and detection
- Fully programmable serial interface characteristics:
 - 5, 6, 7, or 8 data bits
 - Even, odd, stick, or no-parity bit generation/detection
 - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing:
 - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
 - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
 - Support of normal 3/16 and low-power (1.41-2.23 μ s) bit durations
 - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Dedicated DMA transmit and receive channels

13.1 Block Diagram

Figure 13-1. UART Module Block Diagram

13.2 Functional Description

Each Stellaris[®] UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the `TXE` and `RXE` bits of the **UART Control (UARTCTL)** register (see page 371). Transmit and receive are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the `UARTEN` bit in **UARTCTL**. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART peripheral also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the `UARTCTL` register.

13.2.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit, and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 13-2 on page 353 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

Figure 13-2. UART Character Frame

13.2.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divider allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 367) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 368). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (16 * \text{Baud Rate})$$

where *UARTSysClk* is the system clock connected to the UART.

The 6-bit fractional number (that is to be loaded into the *DIVFRAC* bit field in the **UARTFBRD** register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 16x the baud-rate (referred to as *Baud16*). This reference clock is divided by 16 to generate the transmit clock, and is used for error detection during receive operations.

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 369), the **UARTIBRD** and **UARTFBRD** registers form an internal 30-bit register. This internal register is only updated when a write operation to **UARTLCRH** is performed, so any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- **UARTIBRD** write, **UARTFBRD** write, and **UARTLCRH** write
- **UARTFBRD** write, **UARTIBRD** write, and **UARTLCRH** write
- **UARTIBRD** write and **UARTLCRH** write
- **UARTFBRD** write and **UARTLCRH** write

13.2.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the **UARTLCRH** register. Data continues to be transmitted until there is no data left in the transmit

FIFO. The `BUSY` bit in the **UART Flag (UARTFR)** register (see page 364) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The `BUSY` bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the `UnRx` is continuously 1) and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of `Baud16` (described in “Transmit/Receive Logic” on page 352).

The start bit is valid if `UnRx` is still low on the eighth cycle of `Baud16`, otherwise a false start bit is detected and it is ignored. Start bit errors can be viewed in the **UART Receive Status (UARTSR)** register (see page 362). If the start bit was valid, successive data bits are sampled on every 16th cycle of `Baud16` (that is, one bit period later) according to the programmed length of the data characters. The parity bit is then checked if parity mode was enabled. Data length and parity are defined in the **UARTLCRH** register.

Lastly, a valid stop bit is confirmed if `UnRx` is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO, with any error bits associated with that word.

13.2.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream, and half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output, and decoded input to the UART. The UART signal pins can be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as high pulse of 3/16th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW. This drives the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated `IrLPBaud16` signal (1.63 μ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCR** register. See page 366 for more information on IrDA low-power pulse-duration configuration.

Figure 13-3 on page 355 shows the UART transmit and receive signals, with and without IrDA modulation.

Figure 13-3. IrDA Data Modulation

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10 ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased, or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency, or receiver setup time.

13.2.5 FIFO Operation

The UART has two 16-entry FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 360). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the `FEN` bit in **UARTLCRH** (page 369).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 364) and the **UART Receive Status (UARTRSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (`TXFE`, `TXFF`, `RXFE`, and `RXFF` bits) and the **UARTRSR** register shows overrun status via the `OE` bit.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 373). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and $\frac{7}{8}$. For example, if the $\frac{1}{4}$ option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the $\frac{1}{2}$ mark.

13.2.6 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error

- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the `TXIFLSEL` bit in the **UARTIFLS** register is met)
- Receive (when condition defined in the `RXIFLSEL` bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 378).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 375) by setting the corresponding `IM` bit to 1. If interrupts are not used, the raw interrupt status is always visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 377).

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by setting the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 379).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

13.2.7 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the `LBE` bit in the **UARTCTL** register (see page 371). In loopback mode, data transmitted on `UnTx` is received on the `UnRx` input.

13.2.8 DMA Operation

The UART provides an interface connected to the μ DMA controller. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART will assert a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever there is any data in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the μ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, the `RXDMAE` bit of the **DMA Control (UARTDMACTL)** register should be set. To enable DMA operation for the transmit channel, the `TXDMAE` bit of **UARTDMACTL** should be set. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the `DMAERR` bit of **UARTDMACR** is set, then when a receive error occurs, the DMA receive requests will be automatically disabled. This error condition can be cleared by clearing the UART error interrupt.

If DMA is enabled, then the μ DMA controller will trigger an interrupt when a transfer is complete. The interrupt will occur on the UART interrupt vector. Therefore, if interrupts are used for UART

operation and DMA is enabled, the UART interrupt handler must be designed to handle the μ DMA completion interrupt.

See “Micro Direct Memory Access (μ DMA)” on page 156 for more details about programming the μ DMA controller.

13.2.9 IrDA SIR block

The IrDA SIR block contains an IrDA serial IR (SIR) protocol encoder/decoder. When enabled, the SIR block uses the `UnTx` and `UnRx` pins for the SIR protocol, which should be connected to an IR transceiver.

The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception.

13.3 Initialization and Configuration

To use the UART, the peripheral clock must be enabled by setting the `UART0` bit in the `RCGC1` register.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled
- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), since the `UARTIBRD` and `UARTFBRD` registers must be written before the `UARTLCRH` register. Using the equation described in “Baud-Rate Generation” on page 353, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the `DIVINT` field of the `UARTIBRD` register (see page 367) should be set to 10. The value to be loaded into the `UARTFBRD` register (see page 368) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the `UARTEN` bit in the `UARTCTL` register.
2. Write the integer portion of the BRD to the `UARTIBRD` register.
3. Write the fractional portion of the BRD to the `UARTFBRD` register.
4. Write the desired serial parameters to the `UARTLCRH` register (in this case, a value of `0x0000.0060`).

5. Optionally, configure the uDMA channel (see “Micro Direct Memory Access (μDMA)” on page 156) and enable the DMA option(s) in the **UARTDMACTL** register.
6. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

13.4 Register Map

Table 13-1 on page 358 lists the UART registers. The offset listed is a hexadecimal increment to the register’s address, relative to that UART’s base address:

- UART0: 0x4000.C000

Note: The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 371) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

Table 13-1. UART Register Map

13.5 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

Register 1: UART Data (UARTDR), offset 0x000

This register is the data register (the interface to the FIFOs).

When FIFOs are enabled, data written to this location is pushed onto the transmit FIFO. If FIFOs are disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If FIFOs are disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

UART Data (UARTDR)

UART0 base: 0x4000.C000
Offset 0x000
Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:12	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
11	OE	RO	0	UART Overrun Error The OE values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>There has been no data loss due to a FIFO overrun.</td> </tr> <tr> <td>1</td> <td>New data was received when the FIFO was full, resulting in data loss.</td> </tr> </tbody> </table>	Value	Description	0	There has been no data loss due to a FIFO overrun.	1	New data was received when the FIFO was full, resulting in data loss.
Value	Description									
0	There has been no data loss due to a FIFO overrun.									
1	New data was received when the FIFO was full, resulting in data loss.									
10	BE	RO	0	UART Break Error This bit is set to 1 when a break condition is detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits). In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state) and the next valid start bit is received.						
9	PE	RO	0	UART Parity Error This bit is set to 1 when the parity of the received data character does not match the parity defined by bits 2 and 7 of the UARTLCRH register. In FIFO mode, this error is associated with the character at the top of the FIFO.						

Bit/Field	Name	Type	Reset	Description
8	FE	RO	0	UART Framing Error This bit is set to 1 when the received character does not have a valid stop bit (a valid stop bit is 1).
7:0	DATA	R/W	0	Data Transmitted or Received When written, the data that is to be transmitted via the UART. When read, the data that was received by the UART.

Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared to 0 on reset.

Read-Only Receive Status (UARTRSR) Register

UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000

Offset 0x004

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
3	BUSY	RO	0	<p>UART Busy</p> <p>When this bit is 1, the UART is busy transmitting data. This bit remains set until the complete byte, including all stop bits, has been sent from the shift register.</p> <p>This bit is set as soon as the transmit FIFO becomes non-empty (regardless of whether UART is enabled).</p>
2:0	reserved	RO	0	<p>Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.</p>

Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register is an 8-bit read/write register that stores the low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared to 0 when reset.

The internal $F_{IrLPBaud16}$ clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the $F_{IrLPBaud16}$ clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = SysClk / F_{IrLPBaud16}$$

where $F_{IrLPBaud16}$ is nominally 1.8432 MHz.

You must choose the divisor so that $1.42 \text{ MHz} < F_{IrLPBaud16} < 2.12 \text{ MHz}$, which results in a low-power pulse duration of 1.41–2.11 μs (three times the period of $F_{IrLPBaud16}$). The minimum frequency of $F_{IrLPBaud16}$ ensures that pulses less than one period of $F_{IrLPBaud16}$ are rejected, but that pulses greater than 1.4 μs are accepted as valid pulses.

Note: Zero is an illegal value. Programming a zero value results in no $F_{IrLPBaud16}$ pulses being generated.

UART IrDA Low-Power Register (UARTILPR)

UART0 base: 0x4000.C000
 Offset 0x020
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	ILPDVSR	R/W	0x00	IrDA Low-Power Divisor This is an 8-bit low-power divisor value.

Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD=0**), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 353 for configuration details.

UART Integer Baud-Rate Divisor (UARTIBRD)

UART0 base: 0x4000.C000
Offset 0x024
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DIVINT	R/W	0x0000	Integer Baud-Rate Divisor

Register 6: UART Fractional Baud-Rate Divisor (UARTFBRD), offset 0x028

The **UARTFBRD** register is the fractional part of the baud-rate divisor value. All the bits are cleared on reset. When changing the **UARTFBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 353 for configuration details.

UART Fractional Baud-Rate Divisor (UARTFBRD)

UART0 base: 0x4000.C000
 Offset 0x028
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5:0	DIVFRAC	R/W	0x000	Fractional Baud-Rate Divisor

Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

UART Line Control (UARTLCRH)

4	FEN	R/W	0	<p>UART Enable FIFOs</p> <p>If this bit is set to 1, transmit and receive FIFO buffers are enabled (FIFO mode).</p> <p>When cleared to 0, FIFOs are disabled (Character mode). The FIFOs become 1-byte-deep holding registers.</p>										
3	STP2	R/W	0	<p>UART Two Stop Bits Select</p> <p>If this bit is set to 1, two stop bits are transmitted at the end of a frame. The receive logic does not check for two stop bits being received.</p>										

Bit/Field	Name	Type	Reset	Description
2	EPS	R/W	0	<p>UART Even Parity Select</p> <p>If this bit is set to 1, even parity generation and checking is performed during transmission and reception, which checks for an even number of 1s in data and parity bits.</p> <p>When cleared to 0, then odd parity is performed, which checks for an odd number of 1s.</p> <p>This bit has no effect when parity is disabled by the PEN bit.</p>
1	PEN	R/W	0	<p>UART Parity Enable</p> <p>If this bit is set to 1, parity checking and generation is enabled; otherwise, parity is disabled and no parity bit is added to the data frame.</p>
0	BRK	R/W	0	<p>UART Send Break</p> <p>If this bit is set to 1, a Low level is continually output on the UNTX output, after completing transmission of the current character. For the proper execution of the break command, the software must set this bit for at least two frames (character periods). For normal use, this bit must be cleared to 0.</p>

Register 8: UART Control (UARTCTL), offset 0x030

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set to 1.

To enable the UART module, the **UARTEN** bit must be set to 1. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

Note: The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by disabling bit 4 (**FEN**) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

Bit/Field	Name	Type	Reset	Description
31:10	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
9	RXE	R/W	1	<p>UART Receive Enable</p> <p>If this bit is set to 1, the receive section of the UART is enabled. When the UART is disabled in the middle of a receive, it completes the current character before stopping.</p> <p>Note: To enable reception, the UARTEN bit must also be set.</p>
8	TXE	R/W	1	<p>UART Transmit Enable</p> <p>If this bit is set to 1, the transmit section of the UART is enabled. When the UART is disabled in the middle of a transmission, it completes the current character before stopping.</p> <p>Note: To enable transmission, the UARTEN bit must also be set.</p>

Bit/Field	Name	Type	Reset	Description
7	LBE	R/W	0	UART Loop Back Enable If this bit is set to 1, the U_nTX path is fed through the U_nRX path.
6:3	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
2	SIRLP	R/W	0	UART SIR Low Power Mode This bit selects the IrDA encoding mode. If this bit is cleared to 0, low-level bits are transmitted as an active High pulse with a width of 3/16th of the bit period. If this bit is set to 1, low-level bits are transmitted with a pulse width which is 3 times the period of the $I_rLPBaud16$ input signal, regardless of the selected bit rate. Setting this bit uses less power, but might reduce transmission distances. See page 366 for more information.
1	SIREN	R/W	0	UART SIR Enable If this bit is set to 1, the IrDA SIR block is enabled, and the UART will transmit and receive data using SIR protocol.
0	UARTEN	R/W	0	UART Enable If this bit is set to 1, the UART is enabled. When the UART is disabled in the middle of transmission or reception, it completes the current character before stopping.

Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the **TXRIS** and **RXRIS** bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the **TXIFLSEL** and **RXIFLSEL** bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Writing a 1 to a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Writing a 0 prevents the raw interrupt signal from being sent to the interrupt controller.

14 Synchronous Serial Interface (SSI)

The Stellaris[®] Synchronous Serial Interface (SSI) is a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces.

The Stellaris[®] SSI module has the following features:

- Master or slave operation
- Support for Direct Memory Access (DMA)
- Programmable clock bit rate and prescale
- Separate transmit and receive FIFOs, 16 bits wide, 8 locations deep
- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments synchronous serial interfaces
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing

14.1 Block Diagram

Figure 14-1. SSI Module Block Diagram

14.2 Functional Description

The SSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The SSI also supports the DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the DMA module. DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 420).

14.2.1 Bit Rate Generation

The SSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (FSysClk). The clock is first divided by an even prescale value CPDVSr from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 414). The clock is further divided by a value from 1 to 256, which is $1 + SCR$, where *SCR* is the value programmed in the **SSI Control0 (SSICR0)** register (see page 407).

The frequency of the output clock SSIClk is defined by:

$$SSIClk = F_{SysClk} / (CPDVSr * (1 + SCR))$$

Note: Although the SSIClk transmit clock can theoretically be 25 MHz, the module may not be able to operate at that speed. For master mode, the system clock must be at least two times faster than the SSIClk. For slave mode, the system clock must be at least 12 times faster than the SSIClk.

See “Synchronous Serial Interface (SSI)” on page 576 to view SSI timing parameters.

14.2.2 FIFO Operation

14.2.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 411), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to serial conversion and transmission to the attached slave or master, respectively, through the SSITx pin.

14.2.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data from the serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register.

When configured as a master or slave, serial data received through the SSIRx pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

14.2.3 Interrupts

The SSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service
- Receive FIFO service

- Receive FIFO time-out
- Receive FIFO overrun

All of the interrupt events are ORed together before being sent to the interrupt controller, so the SSI can only generate a single interrupt request to the controller at any given time. You can mask each of the four individual maskable interrupts by setting the appropriate bits in the **SSI Interrupt Mask (SSIM)** register (see page 415). Setting the appropriate mask bit to 1 enables the interrupt.

Provision of the individual outputs, as well as a combined interrupt output, allows use of either a global interrupt service routine, or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 417 and page 418, respectively).

14.2.4 Frame Formats

Each data frame is between 4 and 16 bits long, depending on the size of data programmed, and is transmitted starting with the MSB. There are three basic frame types that can be selected:

- Texas Instruments synchronous serial
- Freescale SPI
- MICROWIRE

For all three formats, the serial clock (*SSIClk*) is held inactive while the SSI is idle, and *SSIClk* transitions at the programmed frequency only during active transmission or reception of data. The idle state of *SSIClk* is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI and MICROWIRE frame formats, the serial frame (*SSIFSS*) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the *SSIFSS* pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the SSI and the off-chip slave device drive their output data on the rising edge of *SSIClk*, and latch data from the other device on the falling edge.

Unlike the full-duplex transmission of the other two frame formats, the MICROWIRE format uses a special master-slave messaging technique, which operates at half-duplex. In this mode, when a frame begins, an 8-bit control message is transmitted to the off-chip slave. During this transmit, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the requested data. The returned data can be 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

14.2.4.1 Texas Instruments Synchronous Serial Frame Format

Figure 14-2 on page 397 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

Figure 14-2. TI Synchronous Serial Frame Format (Single Transfer)

In this mode, `SSIClk` and `SSIFss` are forced Low, and the transmit data line `SSITx` is tristated whenever the SSI is idle. Once the bottom entry of the transmit FIFO contains data, `SSIFss` is pulsed High for one `SSIClk` period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of `SSIClk`, the MSB of the 4 to 16-bit data frame is shifted out on the `SSITx` pin. Likewise, the MSB of the received data is shifted onto the `SSIRx` pin by the off-chip serial slave device.

Both the SSI and the off-chip serial slave device then clock each data bit into their serial shifter on the falling edge of each `SSIClk`. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of `SSIClk` after the LSB has been latched.

Figure 14-3 on page 397 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

Figure 14-3. TI Synchronous Serial Frame Format (Continuous Transfer)

14.2.4.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the `SSIFss` signal behaves as a slave select. The main feature of the Freescale SPI format is that the inactive state and phase of the `SSIClk` signal are programmable through the `SPO` and `SPH` bits within the `SSISCR0` control register.

SPO Clock Polarity Bit

When the `SPO` clock polarity control bit is Low, it produces a steady state Low value on the `SSIClk` pin. If the `SPO` bit is High, a steady state High value is placed on the `SSIClk` pin when data is not being transferred.

SPH Phase Control Bit

The `SPH` phase control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the `SPH` phase control bit is Low, data is captured on the first clock edge transition. If the `SPH` bit is High, data is captured on the second clock edge transition.

14.2.4.3 Freescale SPI Frame Format with SPO=0 and SPH=0

Single and continuous transmission signal sequences for Freescale SPI format with SPO=0 and SPH=0 are shown in Figure 14-4 on page 398 and Figure 14-5 on page 398.

Figure 14-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0

Note: Q is undefined.

Figure 14-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. This causes slave data to be enabled onto the SSIRx input line of the master. The master SSITx output pad is enabled.

One half SSIClk period later, valid master data is transferred to the SSITx pin. Now that both the master and slave data have been set, the SSIClk master clock pin goes High after one further half SSIClk period.

The data is now captured on the rising and propagated on the falling edges of the SSIClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the SSIFss line is returned to its idle High state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its

serial peripheral register and does not allow it to be altered if the `SPH` bit is logic zero. Therefore, the master device must raise the `SSIFSS` pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the `SSIFSS` pin is returned to its idle state one `SSIClk` period after the last bit has been captured.

14.2.4.4 Freescale SPI Frame Format with `SPO=0` and `SPH=1`

The transfer signal sequence for Freescale SPI format with `SPO=0` and `SPH=1` is shown in Figure 14-6 on page 399, which covers both single and continuous transfers.

Figure 14-6. Freescale SPI Frame Format with `SPO=0` and `SPH=1`

Note: Q is undefined.

In this configuration, during idle periods:

- `SSIClk` is forced Low
- `SSIFss` is forced High
- The transmit data line `SSITx` is arbitrarily forced Low
- When the SSI is configured as a master, it enables the `SSIClk` pad
- When the SSI is configured as a slave, it disables the `SSIClk` pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the `SSIFss` master signal being driven Low. The master `SSITx` output is enabled. After a further one half `SSIClk` period, both master and slave valid data is enabled onto their respective transmission lines. At the same time, the `SSIClk` is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the `SSIClk` signal.

In the case of a single word transfer, after all bits have been transferred, the `SSIFss` line is returned to its idle High state one `SSIClk` period after the last bit has been captured.

For continuous back-to-back transfers, the `SSIFss` pin is held Low between successive data words and termination is the same as that of the single word transfer.

14.2.4.5 Freescale SPI Frame Format with `SPO=1` and `SPH=0`

Single and continuous transmission signal sequences for Freescale SPI format with `SPO=1` and `SPH=0` are shown in Figure 14-7 on page 400 and Figure 14-8 on page 400.

Figure 14-7. Freescale SPI Frame Format (Single Transfer) with SPO=1 and SPH=0

Note: Q is undefined.

Figure 14-8. Freescale SPI Frame Format (Continuous Transfer) with SPO=1 and SPH=0

In this configuration, during idle periods:

- SSIClk is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low, which causes slave data to be immediately transferred onto the SSIRx line of the master. The master SSITx output pad is enabled.

One half period later, valid master data is transferred to the SSITx line. Now that both the master and slave data have been set, the SSIClk master clock pin becomes Low after one further half SSIClk period. This means that data is captured on the falling edges and propagated on the rising edges of the SSIClk signal.

In the case of a single word transmission, after all bits of the data word are transferred, the SSIFss line is returned to its idle High state one SSIClk period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the SSIFss signal must be pulsed High between each data word transfer. This is because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the SPH bit is logic zero. Therefore, the master device must raise the SSIFss pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the SSIFss pin is returned to its idle state one SSIClk period after the last bit has been captured.

14.2.4.6 Freescale SPI Frame Format with SPO=1 and SPH=1

The transfer signal sequence for Freescale SPI format with SPO=1 and SPH=1 is shown in Figure 14-9 on page 401, which covers both single and continuous transfers.

Figure 14-9. Freescale SPI Frame Format with SPO=1 and SPH=1

Note: Q is undefined.

In this configuration, during idle periods:

- SSIClk is forced High
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low
- When the SSI is configured as a master, it enables the SSIClk pad
- When the SSI is configured as a slave, it disables the SSIClk pad

If the SSI is enabled and there is valid data within the transmit FIFO, the start of transmission is signified by the SSIFss master signal being driven Low. The master SSITx output pad is enabled. After a further one-half SSIClk period, both master and slave data are enabled onto their respective transmission lines. At the same time, SSIClk is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the SSIClk signal.

After all bits have been transferred, in the case of a single word transmission, the SSIFss line is returned to its idle high state one SSIClk period after the last bit has been captured.

For continuous back-to-back transmissions, the SSIFss pin remains in its active Low state, until the final bit of the last word has been captured, and then returns to its idle state as described above.

For continuous back-to-back transfers, the SSIFss pin is held Low between successive data words and termination is the same as that of the single word transfer.

14.2.4.7 MICROWIRE Frame Format

Figure 14-10 on page 402 shows the MICROWIRE frame format, again for a single frame. Figure 14-11 on page 403 shows the same format when back-to-back frames are transmitted.

Figure 14-10. MICROWIRE Frame Format (Single Frame)

MICROWIRE format is very similar to SPI format, except that transmission is half-duplex instead of full-duplex, using a master-slave message passing technique. Each serial transmission begins with an 8-bit control word that is transmitted from the SSI to the off-chip slave device. During this transmission, no incoming data is received by the SSI. After the message has been sent, the off-chip slave decodes it and, after waiting one serial clock after the last bit of the 8-bit control message has been sent, responds with the required data. The returned data is 4 to 16 bits in length, making the total frame length anywhere from 13 to 25 bits.

In this configuration, during idle periods:

- SSIClk is forced Low
- SSIFss is forced High
- The transmit data line SSITx is arbitrarily forced Low

A transmission is triggered by writing a control byte to the transmit FIFO. The falling edge of SSIFss causes the value contained in the bottom entry of the transmit FIFO to be transferred to the serial shift register of the transmit logic, and the MSB of the 8-bit control frame to be shifted out onto the SSITx pin. SSIFss remains Low for the duration of the frame transmission. The SSIRx pin remains tristated during this transmission.

The off-chip serial slave device latches each control bit into its serial shifter on the rising edge of each SSIClk. After the last bit is latched by the slave device, the control byte is decoded during a one clock wait-state, and the slave responds by transmitting data back to the SSI. Each bit is driven onto the SSIRx line on the falling edge of SSIClk. The SSI in turn latches each bit on the rising edge of SSIClk. At the end of the frame, for single transfers, the SSIFss signal is pulled High one clock period after the last bit has been latched in the receive serial shifter, which causes the data to be transferred to the receive FIFO.

Note: The off-chip slave device can tristate the receive line either on the falling edge of SSIClk after the LSB has been latched by the receive shifter, or when the SSIFss pin goes High.

For continuous transfers, data transmission begins and ends in the same manner as a single transfer. However, the SSIFss line is continuously asserted (held Low) and transmission of data occurs back-to-back. The control byte of the next frame follows directly after the LSB of the received data from the current frame. Each of the received values is transferred from the receive shifter on the falling edge of SSIClk, after the LSB of the frame has been latched into the SSI.

Figure 14-11. MICROWIRE Frame Format (Continuous Transfer)

In the MICROWIRE mode, the SSI slave samples the first bit of receive data on the rising edge of SSIClk after SSIFss has gone Low. Masters that drive a free-running SSIClk must ensure that the SSIFss signal has sufficient setup and hold margins with respect to the rising edge of SSIClk.

Figure 14-12 on page 403 illustrates these setup and hold time requirements. With respect to the SSIClk rising edge on which the first bit of receive data is to be sampled by the SSI slave, SSIFss must have a setup of at least two times the period of SSIClk on which the SSI operates. With respect to the SSIClk rising edge previous to this edge, SSIFss must have a hold of at least one SSIClk period.

Figure 14-12. MICROWIRE Frame Format, SSIFss Input Setup and Hold Requirements

14.2.5 DMA Operation

The SSI peripheral provides an interface connected to the μ DMA controller. The DMA operation of the SSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When DMA operation is enabled, the SSI will assert a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever there is any data in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst DMA transfer requests are handled automatically by the μ DMA controller depending how the DMA channel is configured. To enable DMA operation for the receive channel, the **RXDMAE** bit of the **DMA Control (SSIDMACTL)** register should be set. To enable DMA operation for the transmit channel, the **TXDMAE** bit of **SSIDMACTL** should be set. If DMA is enabled, then the μ DMA controller will trigger an interrupt when a transfer is complete. The interrupt will occur on the SSI interrupt vector. Therefore, if interrupts

are used for SSI operation and DMA is enabled, the SSI interrupt handler must be designed to handle the μ DMA completion interrupt.

See “Micro Direct Memory Access (μ DMA)” on page 156 for more details about programming the μ DMA controller.

14.3 Initialization and Configuration

To use the SSI, its peripheral clock must be enabled by setting the *SSI* bit in the **RCGC1** register.

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the *SSE* bit in the **SSICR1** register is disabled before making any configuration changes.
2. Select whether the SSI is a master or slave:
 - a. For master operations, set the **SSICR1** register to 0x0000.0000.
 - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
 - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the clock prescale divisor by writing the **SSICPSR** register.
4. Write the **SSICR0** register with the following configuration:
 - Serial clock rate (*SCR*)
 - Desired clock phase/polarity, if using Freescale SPI mode (*SPH* and *SPO*)
 - The protocol mode: Freescale SPI, TI SSF, MICROWIRE (*FRF*)
 - The data size (*DSS*)
5. Optionally, configure the μ DMA channel (see “Micro Direct Memory Access (μ DMA)” on page 156) and enable the DMA option(s) in the **SSIDMACTL** register.
6. Enable the SSI by setting the *SSE* bit in the **SSICR1** register.

As an example, assume the SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (*SPO*=1, *SPH*=1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$F_{SSIClk} = F_{SysClk} / (CPSDVSR * (1 + SCR))$$

$$1 \times 10^6 = 20 \times 10^6 / (CPSDVSR * (1 + SCR))$$

In this case, if *CPSDVSR*=2, *SCR* must be 9.

The configuration sequence would be as follows:

1. Ensure that the `SSE` bit in the **SSICR1** register is disabled.
2. Write the **SSICR1** register with a value of `0x0000.0000`.
3. Write the **SSICPSR** register with a value of `0x0000.0002`.
4. Write the **SSICR0** register with a value of `0x0000.09C7`.
5. The SSI is then enabled by setting the `SSE` bit in the **SSICR1** register to 1.

14.4 Register Map

Table 14-1 on page 405 lists the SSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that SSI module's base address:

- SSI0: `0x4000.8000`

Note: The SSI must be disabled (see the `SSE` bit in the **SSICR1** register) before any of the control registers are reprogrammed.

Table 14-1. SSI Register Map

Offset	Name	Type	Reset	Description	See page
0x000	SSICR0	R/W	0x0000.0000	SSI Control 0	407
0x004	SSICR1	R/W	0x0000.0000	SSI Control 1	409
0x008	SSIDR	R/W	0x0000.0000	SSI Data	411

14.5 Register Descriptions

The remainder of this section lists and describes the SSI registers, in numerical order by address offset.

Register 1: SSI Control 0 (SSICR0), offset 0x000

SSICR0 is control register 0 and contains bit fields that control various functions within the SSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

SSI Control 0 (SSICR0)

SSI0 base: 0x4000.8000
 Offset 0x000
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:8	SCR	R/W	0x0000	SSI Serial Clock Rate The value <i>SCR</i> is used to generate the transmit and receive bit rate of the SSI. The bit rate is: $BR = FSSIClk / (CPSDVSR * (1 + SCR))$ where <i>CPSDVSR</i> is an even value from 2-254 programmed in the SSICPSR register, and <i>SCR</i> is a value from 0-255.
7	SPH	R/W	0	SSI Serial Clock Phase This bit is only applicable to the Freescale SPI Format. The <i>SPH</i> control bit selects the clock edge that captures data and allows it to change state. It has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the <i>SPH</i> bit is 0, data is captured on the first clock edge transition. If <i>SPH</i> is 1, data is captured on the second clock edge transition.
6	SPO	R/W	0	SSI Serial Clock Polarity This bit is only applicable to the Freescale SPI Format. When the <i>SPO</i> bit is 0, it produces a steady state Low value on the <i>SSIClk</i> pin. If <i>SPO</i> is 1, a steady state High value is placed on the <i>SSIClk</i> pin when data is not being transferred.

Bit/Field	Name	Type	Reset	Description
5:4	FRF	R/W	0x0	SSI Frame Format Select The FRF values are defined as follows: Value Frame Format 0x0 Freescale SPI Frame Format 0x1 Texas Instruments Synchronous Serial Frame Format 0x2 MICROWIRE Frame Format 0x3 Reserved
3:0	DSS	R/W	0x00	SSI Data Size Select The DSS values are defined as follows: Value Data Size 0x0-0x2 Reserved 0x3 4-bit data 0x4 5-bit data 0x5 6-bit data 0x6 7-bit data 0x7 8-bit data 0x8 9-bit data 0x9 10-bit data 0xA 11-bit data 0xB 12-bit data 0xC 13-bit data 0xD 14-bit data 0xE 15-bit data 0xF 16-bit data

Register 2: SSI Control 1 (SSICR1), offset 0x004

SSICR1 is control register 1 and contains bit fields that control various functions within the SSI module. Master and slave mode functionality is controlled by this register.

SSI Control 1 (SSICR1)

SSI0 base: 0x4000.8000
Offset 0x004
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SOD	R/W	0	SSI Slave Mode Output Disable This bit is relevant only in the Slave mode ($MS=1$). In multiple-slave systems, it is possible for the SSI master to broadcast a message to all slaves in the system while ensuring that only one slave drives data onto the serial output line. In such systems, the TXD lines from multiple slaves could be tied together. To operate in such a system, the SOD bit can be configured so that the SSI slave does not drive the $SSITx$ pin. The SOD values are defined as follows: Value Description 0 SSI can drive $SSITx$ output in Slave Output mode. 1 SSI must not drive the $SSITx$ output in Slave mode.
2	MS	R/W	0	SSI Master/Slave Select This bit selects Master or Slave mode and can be modified only when SSI is disabled ($SSE=0$). The MS values are defined as follows: Value Description 0 Device configured as a master. 1 Device configured as a slave.

Bit/Field	Name	Type	Reset	Description						
1	SSE	R/W	0	<p>SSI Synchronous Serial Port Enable</p> <p>Setting this bit enables SSI operation.</p> <p>The <code>SSE</code> values are defined as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>SSI operation disabled.</td></tr><tr><td>1</td><td>SSI operation enabled.</td></tr></tbody></table> <p>Note: This bit must be set to 0 before any control registers are reprogrammed.</p>	Value	Description	0	SSI operation disabled.	1	SSI operation enabled.
Value	Description									
0	SSI operation disabled.									
1	SSI operation enabled.									
0	LBM	R/W	0	<p>SSI Loopback Mode</p> <p>Setting this bit enables Loopback Test mode.</p> <p>The <code>LBM</code> values are defined as follows:</p> <table><thead><tr><th>Value</th><th>Description</th></tr></thead><tbody><tr><td>0</td><td>Normal serial port operation enabled.</td></tr><tr><td>1</td><td>Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.</td></tr></tbody></table>	Value	Description	0	Normal serial port operation enabled.	1	Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.
Value	Description									
0	Normal serial port operation enabled.									
1	Output of the transmit serial shift register is connected internally to the input of the receive serial shift register.									

Register 3: SSI Data (SSIDR), offset 0x008

SSIDR is the data register and is 16-bits wide. When **SSIDR** is read, the entry in the receive FIFO (pointed to by the current FIFO read pointer) is accessed. As data values are removed by the SSI receive logic from the incoming data frame, they are placed into the entry in the receive FIFO (pointed to by the current FIFO write pointer).

When **SSIDR** is written to, the entry in the transmit FIFO (pointed to by the write pointer) is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. It is loaded into the transmit serial shifter, then serially shifted out onto the **SSITx** pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

When the SSI is programmed for MICROWIRE frame format, the default size for transmit data is eight bits (the most significant byte is ignored). The receive data size is controlled by the programmer. The transmit FIFO and the receive FIFO are not cleared even when the **SSE** bit in the **SSICR1** register is set to zero. This allows the software to fill the transmit FIFO before enabling the SSI.

SSI Data (SSIDR)

SSI0 base: 0x4000.8000
Offset 0x008
Type R/W, reset 0x0000.0000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DATA	R/W	0x0000	SSI Receive/Transmit Data A read operation reads the receive FIFO. A write operation writes the transmit FIFO. Software must right-justify data when the SSI is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by the transmit logic. The receive logic automatically right-justifies the data.

Register 4: SSI Status (SSISR), offset 0x00C

SSISR is a status register that contains bits that indicate the FIFO fill status and the SSI busy status.

SSI Status (SSISR)

SSI0 base: 0x4000.8000
 Offset 0x00C
 Type RO, reset 0x0000.0003

Bit/Field	Name	Type	Reset	Description						
31:5	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
4	BSY	RO	0	SSI Busy Bit The BSY values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>SSI is idle.</td> </tr> <tr> <td>1</td> <td>SSI is currently transmitting and/or receiving a frame, or the transmit FIFO is not empty.</td> </tr> </tbody> </table>	Value	Description	0	SSI is idle.	1	SSI is currently transmitting and/or receiving a frame, or the transmit FIFO is not empty.
Value	Description									
0	SSI is idle.									
1	SSI is currently transmitting and/or receiving a frame, or the transmit FIFO is not empty.									
3	RFF	RO	0	SSI Receive FIFO Full The RFF values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Receive FIFO is not full.</td> </tr> <tr> <td>1</td> <td>Receive FIFO is full.</td> </tr> </tbody> </table>	Value	Description	0	Receive FIFO is not full.	1	Receive FIFO is full.
Value	Description									
0	Receive FIFO is not full.									
1	Receive FIFO is full.									
2	RNE	RO	0	SSI Receive FIFO Not Empty The RNE values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Receive FIFO is empty.</td> </tr> <tr> <td>1</td> <td>Receive FIFO is not empty.</td> </tr> </tbody> </table>	Value	Description	0	Receive FIFO is empty.	1	Receive FIFO is not empty.
Value	Description									
0	Receive FIFO is empty.									
1	Receive FIFO is not empty.									
1	TNF	RO	1	SSI Transmit FIFO Not Full The TNF values are defined as follows: <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Transmit FIFO is full.</td> </tr> <tr> <td>1</td> <td>Transmit FIFO is not full.</td> </tr> </tbody> </table>	Value	Description	0	Transmit FIFO is full.	1	Transmit FIFO is not full.
Value	Description									
0	Transmit FIFO is full.									
1	Transmit FIFO is not full.									

Bit/Field	Name	Type	Reset	Description
0	TFE	R0	1	SSI Transmit FIFO Empty The TFE values are defined as follows: Value Description 0 Transmit FIFO is not empty. 1 Transmit FIFO is empty.

Register 5: SSI Clock Prescale (SSICPSR), offset 0x010

SSICPSR is the clock prescale register and specifies the division factor by which the system clock must be internally divided before further use.

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

SSI Clock Prescale (SSICPSR)

SSI0 base: 0x4000.8000
 Offset 0x010
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	CPSDVSR	R/W	0x00	SSI Clock Prescale Divisor This value must be an even number from 2 to 254, depending on the frequency of SSI0CLK. The LSB always returns 0 on reads.

Register 6: SSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared to 0 on reset.

On a read, this register gives the current value of the mask on the relevant interrupt. A write of 1 to the particular bit sets the mask, enabling the interrupt to be read. A write of 0 clears the corresponding mask.

SSI Interrupt Mask (SSIIM)

SSI0 base: 0x4000.8000
Offset 0x014
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXIM	R/W	0	SSI Transmit FIFO Interrupt Mask The TXIM values are defined as follows: Value Description 0 TX FIFO half-full or less condition interrupt is masked. 1 TX FIFO half-full or less condition interrupt is not masked.
2	RXIM	R/W	0	SSI Receive FIFO Interrupt Mask The RXIM values are defined as follows: Value Description 0 RX FIFO half-full or more condition interrupt is masked. 1 RX FIFO half-full or more condition interrupt is not masked.
1	RTIM	R/W	0	SSI Receive Time-Out Interrupt Mask The RTIM values are defined as follows: Value Description 0 RX FIFO time-out interrupt is masked. 1 RX FIFO time-out interrupt is not masked.

Bit/Field	Name	Type	Reset	Description
0	RORIM	R/W	0	SSI Receive Overrun Interrupt Mask The RORIM values are defined as follows: Value Description 0 RX FIFO overrun interrupt is masked. 1 RX FIFO overrun interrupt is not masked.

Register 7: SSI Raw Interrupt Status (SSIRIS), offset 0x018

The **SSIRIS** register is the raw interrupt status register. On a read, this register gives the current raw status value of the corresponding interrupt prior to masking. A write has no effect.

SSI Raw Interrupt Status (SSIRIS)

SSI0 base: 0x4000.8000
Offset 0x018
Type RO, reset 0x0000.0008

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	TXMIS	RO	0	SSI Transmit FIFO Masked Interrupt Status Indicates that the transmit FIFO is half full or less, when set.
2	RXMIS	RO	0	SSI Receive FIFO Masked Interrupt Status Indicates that the receive FIFO is half full or more, when set.
1	RTMIS	RO	0	SSI Receive Time-Out Masked Interrupt Status Indicates that the receive time-out has occurred, when set.
0	RORMIS	RO	0	SSI Receive Overrun Masked Interrupt Status Indicates that the receive FIFO has overflowed, when set.

Register 9: SSI Interrupt Clear (SSIICR), offset 0x020

The **SSIICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt is cleared. A write of 0 has no effect.

SSI Interrupt Clear (SSIICR)

SSI0 base: 0x4000.8000

Offset 0x020

Type W1C, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	RTIC	W1C	0	SSI Receive Time-Out Interrupt Clear The RTIC values are defined as follows: Value Description 0 No effect on interrupt. 1 Clears interrupt.
0	RORIC	W1C	0	SSI Receive Overrun Interrupt Clear The RORIC values are defined as follows: Value Description 0 No effect on interrupt. 1 Clears interrupt.

Register 10: SSI DMA Control (SSIDMACTL), offset 0x024

The **SSIDMACTL** register is the DMA control register.

SSI DMA Control (SSIDMACTL)

SSI0 base: 0x4000.8000
 Offset 0x024
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	TXDMAE	R/W	0	Transmit DMA Enable If this bit is set to 1, DMA for the transmit FIFO is enabled.
0	RXDMAE	R/W	0	Receive DMA Enable If this bit is set to 1, DMA for the receive FIFO is enabled.

Register 11: SSI Peripheral Identification 4 (SSIPeriphID4), offset 0xFD0

The **SSIPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

SSI Peripheral Identification 4 (SSIPeriphID4)

SSI0 base: 0x4000.8000

Offset 0xFD0

Type RO, reset 0x0000.0000

15 Inter-Integrated Circuit (I²C) Interface

The Inter-Integrated Circuit (I²C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I²C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I²C bus may also be used for system testing and diagnostic purposes in product development and manufacture. The LM3S2671 microcontroller includes one I²C module, providing the ability to interact (both send and receive) with other I²C devices on the bus.

Devices on the I²C bus can be designated as either a master or a slave. The Stellaris[®] I²C module supports both sending and receiving data as either a master or a slave, and also supports the simultaneous operation as both a master and a slave. There are a total of four I²C modes: Master Transmit, Master Receive, Slave Transmit, and Slave Receive. The Stellaris[®] I²C module can operate at two speeds: Standard (100 Kbps) and Fast (400 Kbps).

Both the I²C master and slave can generate interrupts; the I²C master generates interrupts when a transmit or receive operation completes (or aborts due to an error) and the I²C slave generates interrupts when data has been sent or requested by a master.

15.1 Block Diagram

Figure 15-1. I²C Block Diagram

15.2 Functional Description

The I²C module is comprised of both master and slave functions which are implemented as separate peripherals. For proper operation, the SDA and SCL pins must be connected to bi-directional open-drain pads. A typical I²C bus configuration is shown in Figure 15-2 on page 434.

See "I²C" on page 576 for I²C timing diagrams.

Figure 15-2. I²C Bus Configuration

15.2.1 I²C Bus Functional Overview

The I²C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on Stellaris[®] microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are high.

Every transaction on the I²C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 434) is unrestricted, but each byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

15.2.1.1 START and STOP Conditions

The protocol of the I²C bus defines two states to begin and end a transaction: START and STOP. A high-to-low transition on the SDA line while the SCL is high is defined as a START condition, and a low-to-high transition on the SDA line while SCL is high is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 15-3 on page 434.

Figure 15-3. START and STOP Conditions

When operating in slave mode, two bits in the **I2CRIS** register indicate detection of start and stop conditions on the bus; while two bits in the **I2CSMIS** register allow start and stop conditions to be promoted to controller interrupts (when interrupts are enabled).

15.2.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 15-4 on page 435. After the START condition, a slave address is sent. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). A zero indicates a transmit operation (send), and a one indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a

STOP condition. Various combinations of receive/send formats are then possible within a single transfer.

Figure 15-4. Complete Data Transfer with a 7-Bit Address

The first seven bits of the first byte make up the slave address (see Figure 15-5 on page 435). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master will write (send) data to the selected slave, and a one in this position means that the master will receive data from the slave.

Figure 15-5. R/S Bit in First Byte

15.2.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is low (see Figure 15-6 on page 435).

Figure 15-6. Data Validity During Bit Transfer on the I²C Bus

15.2.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data sent out by the receiver during the acknowledge cycle must comply with the data validity requirements described in "Data Validity" on page 435.

When a slave receiver does not acknowledge the slave address, SDA must be left high by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Since the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

15.2.1.5 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is high. During arbitration, the first of the competing master devices to place a '1' (high) on SDA while another master transmits a '0' (low) will switch off its data output stage and retire until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

15.2.2 Available Speed Modes

The I²C clock rate is determined by the parameters: CLK_PRD, TIMER_PRD, SCL_LP, and SCL_HP. where:

CLK_PRD is the system clock period

SCL_LP is the low phase of SCL (fixed at 6)

SCL_HP is the high phase of SCL (fixed at 4)

TIMER_PRD is the programmed value in the **I²C Master Timer Period (I2CMTPR)** register (see page 453).

The I²C clock period is calculated as follows:

$$SCL_PERIOD = 2 * (1 + TIMER_PRD) * (SCL_LP + SCL_HP) * CLK_PRD$$

For example:

CLK_PRD = 50 ns

TIMER_PRD = 2

SCL_LP=6

SCL_HP=4

yields a SCL frequency of:

$$1/T = 333 \text{ Khz}$$

Table 15-1 on page 436 gives examples of timer period, system clock, and speed mode (Standard or Fast).

Table 15-1. Examples of I²C Master Timer Period versus Speed Mode

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode
4 Mhz	0x01	100 Kbps	-	-
6 Mhz	0x02	100 Kbps	-	-
12.5 Mhz	0x06	89 Kbps	0x01	312 Kbps
16.7 Mhz	0x08	93 Kbps	0x02	278 Kbps
20 Mhz	0x09	100 Kbps	0x02	333 Kbps
25 Mhz	0x0C	96.2 Kbps	0x03	312 Kbps
33Mhz	0x10	97.1 Kbps	0x04	330 Kbps
40Mhz	0x13	100 Kbps	0x04	400 Kbps

System Clock	Timer Period	Standard Mode	Timer Period	Fast Mode
50MHz	0x18	100 Kbps	0x06	357 Kbps

15.2.3 Interrupts

The I²C can generate interrupts when the following conditions are observed:

- Master transaction completed
- Master transaction error
- Slave transaction received
- Slave transaction requested
- Stop condition on bus detected
- Start condition on bus detected

There is a separate interrupt signal for the I²C master and I²C slave modules. While both modules can generate interrupts for multiple conditions, only a single interrupt signal is sent to the interrupt controller.

15.2.3.1 I²C Master Interrupts

The I²C master module generates an interrupt when a transaction completes (either transmit or receive), or when an error occurs during a transaction. To enable the I²C master interrupt, software must write a '1' to the **I²C Master Interrupt Mask (I2CMIMR)** register. When an interrupt condition is met, software must check the `ERROR` bit in the **I²C Master Control/Status (I2CMCS)** register to verify that an error didn't occur during the last transaction. An error condition is asserted if the last transaction wasn't acknowledge by the slave or if the master was forced to give up ownership of the bus due to a lost arbitration round with another master. If an error is not detected, the application can proceed with the transfer. The interrupt is cleared by writing a '1' to the **I²C Master Interrupt Clear (I2CMICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I²C Master Raw Interrupt Status (I2CMRIS)** register.

15.2.3.2 I²C Slave Interrupts

The slave module generates interrupts as it receives data and transmit requests from an I²C master. The slave module also generates interrupts when a start and stop condition is detected. To enable an I²C slave interrupt, write a '1' to the appropriate bit in the **I²C Slave Interrupt Mask (I2CSIMR)** register. Software determines whether the module should write (transmit) or read (receive) data from the **I²C Slave Data (I2CSDR)** register, by checking the `RREQ` and `TREQ` bits of the **I²C Slave Control/Status (I2CCSR)** register. If the slave module is in receive mode and the first byte of a transfer is received, the `FBR` bit is set along with the `RREQ` bit. The interrupt is cleared by writing a '1' to the **I²C Slave Interrupt Clear (I2CSICR)** register.

If the application doesn't require the use of interrupts, the raw interrupt status is always visible via the **I²C Slave Raw Interrupt Status (I2CSRIS)** register.

15.2.4 Loopback Operation

The I²C modules can be placed into an internal loopback mode for diagnostic or debug work. This is accomplished by setting the `LPBK` bit in the **I²C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and slave modules are tied together.

15.2.5 Command Sequence Flow Charts

This section details the steps required to perform the various I²C transfer types in both master and slave mode.

15.2.5.1 I²C Master Command Sequences

The figures that follow show the command sequences available for the I²C master.

Figure 15-7. Master Single SEND

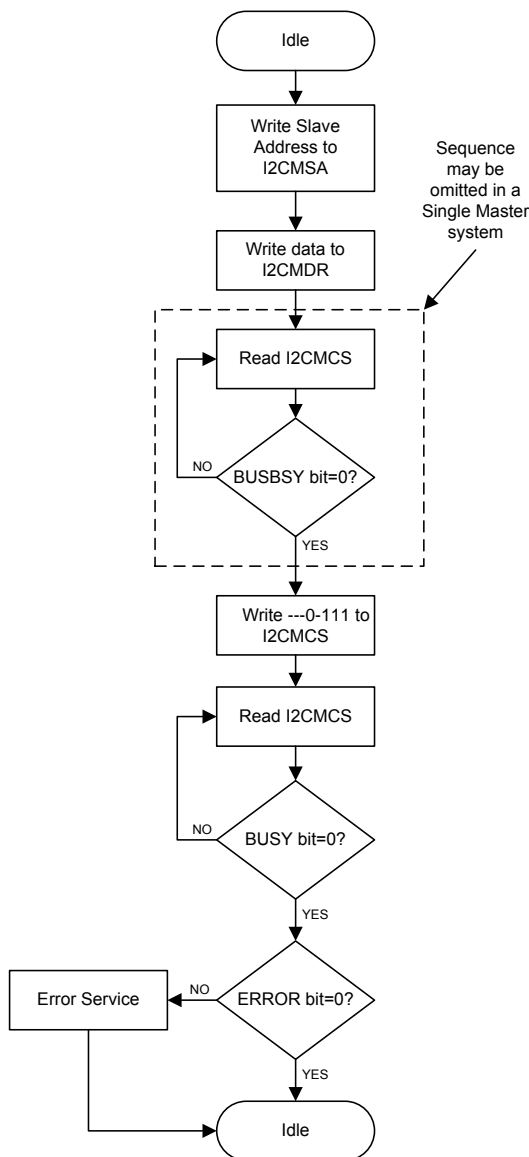

Figure 15-8. Master Single RECEIVE

Figure 15-9. Master Burst SEND

Figure 15-10. Master Burst RECEIVE

Figure 15-12. Master Burst SEND after Burst RECEIVE

15.2.5.2 I²C Slave Command Sequences

Figure 15-13 on page 444 presents the command sequence available for the I²C slave.

Figure 15-13. Slave Command Sequence

15.3 Initialization and Configuration

The following example shows how to configure the I²C module to send a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I²C clock by writing a value of 0x0000.1000 to the **RCGC1** register in the System Control module.
2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. Also, be sure to enable the same pins for Open Drain operation.
4. Initialize the I²C Master by writing the **I2CMCR** register with a value of 0x0000.0020.
5. Set the desired SCL clock speed of 100 Kbps by writing the **I2CMTPR** register with the correct value. The value written to the **I2CMTPR** register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```

TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;
TPR = (20MHz / (2 * (6 + 4) * 100000)) - 1;
TPR = 9

```

Write the **I2CMTPR** register with the value of 0x0000.0009.

6. Specify the slave address of the master and that the next operation will be a Send by writing the **I2CMSA** register with a value of 0x0000.0076. This sets the slave address to 0x3B.
7. Place data (byte) to be sent in the data register by writing the **I2CMDR** register with the desired data.
8. Initiate a single byte send of the data from Master to Slave by writing the **I2CMCS** register with a value of 0x0000.0007 (STOP, START, RUN).
9. Wait until the transmission completes by polling the **I2CMCS** register's **BUSBSY** bit until it has been cleared.

15.4 I²C Register Map

Table 15-2 on page 445 lists the I²C registers. All addresses given are relative to the I²C base addresses for the master and slave:

- I²C Master 0: 0x4002.0000
- I²C Slave 0: 0x4002.0800

15.5 Register Descriptions (I²C Master)

The remainder of this section lists and describes the I²C master registers, in numerical order by address offset. See also “Register Descriptions (I2C Slave)” on page 459.

Register 1: I²C Master Slave Address (I2CMSA), offset 0x000

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Send (Low).

I2C Master Slave Address (I2CMSA)

I2C Master 0 base: 0x4002.0000

Offset 0x000

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:1	SA	R/W	0	I ² C Slave Address This field specifies bits A6 through A0 of the slave address.
0	R/S	R/W	0	Receive/Send The R/S bit specifies if the next operation is a Receive (High) or Send (Low). Value Description 0 Send. 1 Receive.

Register 2: I²C Master Control/Status (I2CMCS), offset 0x004

This register accesses four control bits when written, and accesses seven status bits when read.

The status register consists of seven bits, which when read determine the state of the I²C bus controller.

The control register consists of four bits: the RUN, START, STOP, and ACK bits. The START bit causes the generation of the START, or REPEATED START condition.

The STOP bit determines if the cycle stops at the end of the data cycle, or continues on to a burst. To generate a single send cycle, the I²C Master Slave Address (I2CMSA) register is written with the desired address, the R/S bit is set to 0, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due an error), the interrupt pin becomes active and the data may be read from the I2CMDR register. When the I²C module operates in Master receiver mode, the ACK bit must be set normally to logic 1. This causes the I²C bus controller to send an acknowledge automatically after each byte. This bit must be reset when the I²C bus controller requires no further data to be sent from the slave transmitter.

Read-Only Status Register

I2C Master Control/Status (I2CMCS)

I2C Master 0 base: 0x4002.0000

Offset 0x004

Type RO, reset 0x0000.0000

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
	reserved										BUSBSY	IDLE	ARBLST	DATAACK	ADRACK	ERROR	BUSY
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6	BUSBSY	RO	0	Bus Busy This bit specifies the state of the I ² C bus. If set, the bus is busy; otherwise, the bus is idle. The bit changes based on the START and STOP conditions.
5	IDLE	RO	0	I ² C Idle This bit specifies the I ² C controller state. If set, the controller is idle; otherwise the controller is not idle.
4	ARBLST	RO	0	Arbitration Lost This bit specifies the result of bus arbitration. If set, the controller lost arbitration; otherwise, the controller won arbitration.

Bit/Field	Name	Type	Reset	Description
3	DATAACK	RO	0	Acknowledge Data This bit specifies the result of the last data operation. If set, the transmitted data was not acknowledged; otherwise, the data was acknowledged.
2	ADRACK	RO	0	Acknowledge Address This bit specifies the result of the last address operation. If set, the transmitted address was not acknowledged; otherwise, the address was acknowledged.
1	ERROR	RO	0	Error This bit specifies the result of the last bus operation. If set, an error occurred on the last operation; otherwise, no error was detected. The error can be from the slave address not being acknowledged, the transmit data not being acknowledged, or because the controller lost arbitration.
0	BUSY	RO	0	I ² C Busy This bit specifies the state of the controller. If set, the controller is busy; otherwise, the controller is idle. When the <code>BUSY</code> bit is set, the other status bits are not valid.

Write-Only Control Register

I2C Master Control/Status (I2CMCS)

I2C Master 0 base: 0x4002.0000
Offset 0x004
Type WO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:4	reserved	WO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	ACK	WO	0	Data Acknowledge Enable When set, causes received data byte to be acknowledged automatically by the master. See field decoding in Table 15-3 on page 450.
2	STOP	WO	0	Generate STOP When set, causes the generation of the STOP condition. See field decoding in Table 15-3 on page 450.

Bit/Field	Name	Type	Reset	Description
1	START	WO	0	Generate START When set, causes the generation of a START or repeated START condition. See field decoding in Table 15-3 on page 450.
0	RUN	WO	0	I ² C Master Enable When set, allows the master to send or receive data. See field decoding in Table 15-3 on page 450.

Table 15-3. Write Field Decoding for I2CMCS[3:0] Field (Sheet 1 of 3)

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
	R/S	ACK	STOP	START	RUN	
Idle	0	X ^a	0	1	1	START condition followed by SEND (master goes to the Master Transmit state).
	0	X	1	1	1	START condition followed by a SEND and STOP condition (master remains in Idle state).
	1	0	0	1	1	START condition followed by RECEIVE operation with negative ACK (master goes to the Master Receive state).
	1	0	1	1	1	START condition followed by RECEIVE and STOP condition (master remains in Idle state).
	1	1	0	1	1	START condition followed by RECEIVE (master goes to the Master Receive state).
	1	1	1	1	1	Illegal.
	All other combinations not listed are non-operations.					
Master Transmit	X	X	0	0	1	SEND operation (master remains in Master Transmit state).
	X	X	1	0	0	STOP condition (master goes to Idle state).
	X	X	1	0	1	SEND followed by STOP condition (master goes to Idle state).
	0	X	0	1	1	Repeated START condition followed by a SEND (master remains in Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by SEND and STOP condition (master goes to Idle state).
	1	0	0	1	1	Repeated START condition followed by a RECEIVE operation with a negative ACK (master goes to Master Receive state).
	1	0	1	1	1	Repeated START condition followed by a SEND and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master goes to Master Receive state).
	1	1	1	1	1	Illegal.
	All other combinations not listed are non-operations.					

Current State	I2CMSA[0]	I2CMCS[3:0]				Description
	R/S	ACK	STOP	START	RUN	
Master Receive	X	0	0	0	1	RECEIVE operation with negative ACK (master remains in Master Receive state).
	X	X	1	0	0	STOP condition (master goes to Idle state). ^b
	X	0	1	0	1	RECEIVE followed by STOP condition (master goes to Idle state).
	X	1	0	0	1	RECEIVE operation (master remains in Master Receive state).
	X	1	1	0	1	Illegal.
	1	0	0	1	1	Repeated START condition followed by RECEIVE operation with a negative ACK (master remains in Master Receive state).
	1	0	1	1	1	Repeated START condition followed by RECEIVE and STOP condition (master goes to Idle state).
	1	1	0	1	1	Repeated START condition followed by RECEIVE (master remains in Master Receive state).
	0	X	0	1	1	Repeated START condition followed by SEND (master goes to Master Transmit state).
	0	X	1	1	1	Repeated START condition followed by SEND and STOP condition (master goes to Idle state).
All other combinations not listed are non-operations.						NOP.

a. An X in a table cell indicates the bit can be 0 or 1.

b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

Register 3: I²C Master Data (I2CMDR), offset 0x008

This register contains the data to be transmitted when in the Master Transmit state, and the data received when in the Master Receive state.

I2C Master Data (I2CMDR)

I2C Master 0 base: 0x4002.0000

Offset 0x008

31:8	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	TPR	R/W	0x1	SCL Clock Period

This field specifies the period of the SCL clock.

$$SCL_PRD = 2 * (1 + TPR) * (SCL_LP + SCL_HP) * CLK_PRD$$

where:

SCL_PRD is the SCL line period (I²C clock).

TPR is the Timer Period register value (range of 1 to 255).

SCL_LP is the SCL Low period (fixed at 6).

SCL_HP is the SCL High period (fixed at 4).

Register 5: I²C Master Interrupt Mask (I2CMIMR), offset 0x010

This register controls whether a raw interrupt is promoted to a controller interrupt.

I2C Master Interrupt Mask (I2CMIMR)

I2C Master 0 base: 0x4002.0000

Offset 0x010

Type R/W, reset 0x0000.0000

31:6	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
5	SFE	R/W	0	I ² C Slave Function Enable This bit specifies whether the interface may operate in Slave mode. If set, Slave mode is enabled; otherwise, Slave mode is disabled.
4	MFE	R/W	0	I ² C Master Function Enable This bit specifies whether the interface may operate in Master mode. If set, Master mode is enabled; otherwise, Master mode is disabled and the interface clock is disabled.
3:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	LPBK	R/W	0	I ² C Loopback This bit specifies whether the interface is operating normally or in Loopback mode. If set, the device is put in a test mode loopback configuration; otherwise, the device operates normally.

15.6 Register Descriptions (I2C Slave)

The remainder of this section lists and describes the I²C slave registers, in numerical order by address offset. See also “Register Descriptions (I²C Master)” on page 446.

Register 10: I²C Slave Own Address (I2CSOAR), offset 0x000

This register consists of seven address bits that identify the Stellaris[®] I²C device on the I²C bus.

I2C Slave Own Address (I2CSOAR)

I2C Slave 0 base: 0x4002.0800

Offset 0x000

Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:7	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
6:0	OAR	R/W	0x00	I ² C Slave Own Address This field specifies bits A6 through A0 of the slave address.

Register 11: I²C Slave Control/Status (I2CCSR), offset 0x004

This register accesses one control bit when written, and three status bits when read.

The read-only Status register consists of three bits: the `FBR`, `RREQ`, and `TREQ` bits. The `First Byte Received (FBR)` bit is set only after the Stellaris[®] device detects its own slave address and receives the first data byte from the I²C master. The `Receive Request (RREQ)` bit indicates that the Stellaris[®] I²C device has received a data byte from an I²C master. Read one data byte from the **I²C Slave Data (I2CSDR)** register to clear the `RREQ` bit. The `Transmit Request (TREQ)` bit indicates that the Stellaris[®] I²C device is addressed as a Slave Transmitter. Write one data byte into the **I²C Slave Data (I2CSDR)** register to clear the `TREQ` bit.

The write-only Control register consists of one bit: the `DA` bit. The `DA` bit enables and disables the Stellaris[®] I²C slave operation.

Read-Only Status Register

I2C Slave Control/Status (I2CCSR)

16 Controller Area Network (CAN) Module

16.1 Controller Area Network Overview

Controller Area Network (CAN) is a multicast shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths below 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 m).

16.2 Controller Area Network Features

The Stellaris[®] CAN module supports the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects
- Each message object has its own identifier mask
- Maskable interrupt
- Disable Automatic Retransmission mode for Time Triggered CAN (TTCAN) applications
- Programmable Loopback mode for self-test operation
- Programmable FIFO mode
- Gluelessly attachable to an external CAN PHY through the CAN0Tx and CAN0Rx pins

16.3 Controller Area Network Block Diagram

Figure 16-1. CAN Module Block Diagram

16.4 Controller Area Network Functional Description

The CAN module conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These are accessed via the CAN message object register interface. The message memory is not directly accessible in the Stellaris[®] memory map, so the Stellaris[®] CAN controller provides an interface to communicate with the message memory.

The CAN message object register interface provides two register sets for communicating with the message objects. Since there is no direct access to the message object memory, these two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that needs to be processed.

16.4.1 Initialization

The software initialization is started by setting the `INIT` bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While `INIT` is set, all message transfers to and from the CAN bus are stopped and the status of the CAN transmit output is recessive (High). Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible when in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, it is sufficient to set it as not valid by clearing the `MsgVal` bit in the **CANIFnARB2** register. Otherwise, the whole message object has to be initialized, as the fields of the message object may not have valid information, causing unexpected results. Access to the **CAN Bit Timing (CANBIT)** register and to the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing is enabled when both the `INIT` and `CCE` bits in the **CANCTL** register are set. To leave the initialization state, the `INIT` bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus Idle) before it takes part in bus activities and starts message transfers. The initialization of the message objects is independent of being in the initialization state and can be done on the fly, but message objects should all be configured to particular identifiers or set to not valid before the BSP starts the message transfer. To change the configuration of a message object during normal operation, set the `MsgVal` bit in the **CANIFnARB2** register to 0 (not valid). When the configuration is completed, `MsgVal` is set to 1 again (valid).

16.4.2 Operation

Once the CAN module is initialized and the `INIT` bit in the **CANCTL** register is reset to 0, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As messages are received, they are stored in their appropriate message objects if they pass the message handler's filtering. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the `MSK` bits in the **CANIFnMSKn** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers (**CANIFnCRQ**, **CANIFnCMSK**, **CANIFnMSKn**, **CANIFnARBn**, **CANIFnMCTL**, **CANIFnDAn**, and **CANIFnDBn**). The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. These can be message objects used for one-time data transfers, or permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. To start the transmission, the `TxRqst` bit in the **CANTXRQn** register and the `NewDat` bit in the **CANNWDAn** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not

sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier for the message object. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

There are two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**), which are used to access the Message Objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The function of the two sets are independent and identical and can be used to queue transactions.

16.4.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if there is no data transfer between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's *NewDat* bit is reset and can be viewed in the **CANNWDAn** register. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the *TxRqst* bit in the **CANIFnCMSK** register is reset. If the *TxIE* bit in the **CANIFnMCTL** register is set, the *IntPnd* bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

16.4.4 Configuring a Transmit Message Object

Table 16-1 on page 471 specifies the bit settings for a transmit message object.

Table 16-1. Transmit Message Object Bit Settings

Register	CANIFnARB2			CANIFnCMSK		CANIFnMCTL	CANIFnARB2	CANIFnMCTL					
Bit	MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
Value	1	appl	appl	appl	1	1	0	0	0	appl	0	appl	0

The *xtd* and *ID* bit fields in the **CANIFnARBn** registers are set by an application. They define the identifier and type of the outgoing message. If an 11-bit Identifier (Standard Frame) is used, it is programmed to bits [12:2] of **CANIFnARB2**, and the remaining identifier bits are not used by the CAN controller.

If the *TxIE* bit is set, the *IntPnd* bit is set after a successful transmission of the message object.

When the *RmtEn* bit is set, a matching received remote frame causes the *TxRqst* bit to be set and the message object automatically transfers the message object's data or generates an interrupt indicating a remote frame was requested. This can be strictly a single message identifier or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The *UMask* bit in the **CANIFnMCTL** register enables the *MSk* bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The *Mxtd* bit should be set if only 29-bit extended identifiers should trigger a remote frame request.

The `DLC` bit in the **CANIFnMCTL** register is set to the number of bytes to transfer to the message object. `TxRqst` and `RmtEn` should not be set before the data is valid, as the current data in the message object can be transmitted as soon as these bits are set.

16.4.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the `MsgVal` nor the `TxRqst` bits have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn** or **CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the **CANIFnDAn** or **CANIFnDBn** register or the message object is transferred to the **CANIFnDAn** or **CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the `WR`, `NewDat`, `DataA`, and `DataB` bits are written to the **CAN IFn Command Mask (CANIFnMSKn)** register, followed by writing the **CAN IFn Data** registers, and then the number of the message object is written to the **CAN IFn Command Request (CANIFnCRQ)** register, to update the data bytes and the `TxRqst` bit at the same time.

To prevent the reset of `TxRqst` at the end of a transmission that may already be in progress while the data is updated, `NewDat` has to be set together with `TxRqst`. When `NewDat` is set together with `TxRqst`, `NewDat` is reset as soon as the new transmission has started.

16.4.6 Accepting Received Message Objects

When the arbitration and control field (`ID + Xtd + RmtEn + DLC`) of an incoming message is completely shifted into the CAN module, the message handling capability of the module starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the Acceptance Filtering unit is loaded with the arbitration bits from the core. Then the arbitration and mask fields (including `MsgVal`, `UMask`, `NewDat`, and `EoB`) of message object 1 are loaded into the Acceptance Filtering unit and compared with the arbitration field from the shift register. This is repeated with each following message object until a matching message object is found or until the end of the message RAM is reached. If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of frame received.

16.4.7 Receiving a Data Frame

The message handler stores the message from the CAN module receive shift register into the respective message object in the message RAM. It stores the data bytes, all arbitration bits, and the Data Length Code into the corresponding message object. This is implemented to keep the data bytes connected with the identifier even if arbitration mask registers are used. The `NewDat` bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should reset this bit when it reads the message object to indicate to the controller that the message has been received and the buffer is free to receive more messages. If the CAN controller receives a message and the `NewDat` bit was already set, the `MsgLst` bit is set to indicate that the previous data was lost. If the `RxIE` bit of the **CANIFnMCTL** register is set, the `IntPnd` bit of the same register is set, causing the **CANINT** interrupt register to point to the message object that just received a message. The `TxRqst` bit of this message object should be cleared to prevent the transmission of a remote frame.

16.4.8 Receiving a Remote Frame

When a remote frame is received, three different configurations of the matching message object have to be considered:

Configuration	Description
Dir = 1 (direction = transmit) RmtEn = 1 UMask = 1 or 0	At the reception of a matching remote frame, the TxRqst bit of this message object is set. The rest of the message object remains unchanged, and the controller will transfer the data in the message object.
Dir = 1 (direction = transmit) RmtEn = 0 UMask = 0	At the reception of a matching remote frame, the TxRqst bit of this message object remains unchanged; the remote frame is ignored. This remote frame is disabled and will not automatically respond or indicate that the remote frame ever happened.
Dir = 1 (direction = transmit) RmtEn = 0 UMask = 1	At the reception of a matching remote frame, the TxRqst bit of this message object is reset. The arbitration and control field (ID + Xtd + RmtEn + DLC) from the shift register is stored into the message object in the message RAM and the NewDat bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This is useful for a remote data request from another CAN device for which the Stellaris [®] controller does not have readily available data. The software must fill the data and answer the frame manually.

16.4.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This should not be confused with the message identifier as that priority is enforced by the CAN bus. This means that if message object 1 and message object 2 both have valid messages that need to be transmitted, message object 1 will always be transmitted first regardless of the message identifier in the message object itself.

16.4.10 Configuring a Receive Message Object

Table 16-2 on page 473 specifies the bit settings for a transmit message object.

Table 16-2. Receive Message Object Bit Settings

Register	CANIFnARBN				CANIFnMCTL								
	MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
Value	1	appl	appl	appl	1	0	0	0	appl	0	0	0	0

The Xtd and ID bit fields in the **CANIFnARBN** registers are set by an application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (Standard Frame) is used, it is programmed to bits [12:2] of **CANIFnARBN**, and the remaining identifier bits are ignored by the CAN controller. When a data frame with an 11-bit Identifier is received, only bits 12:2 of **CANIFnARBN** are valid and the rest are set to 0.

If the RxIE bit is set, the IntPnd bit is set when a received data frame is accepted and stored in the message object.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKN**, configure which groups of frames are received by a message object. The UMask bit in the **CANIFnMCTL** register enables the Msk bits in the **CANIFnMSKN** register to filter which frames are received. The MXtd bit should be set if only 29-bit extended identifiers should be received by this message object.

16.4.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CAN IFn Command Mask (CANIFnCMSK)** register and then writes the number of the message object to the **CAN IFn Command Request (CANIFnCRQ)** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the `NewDat` and `IntPnd` bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt being generated by this message object.

If the message object uses masks for acceptance filtering, the arbitration bits show which of the matching messages has been received.

The actual value of `NewDat` shows whether a new message has been received since the last time this message object was read. The actual value of `MsgLst` shows whether more than one message has been received since the last time this message object was read. `MsgLst` is not automatically reset.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the `TxRqst` bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the `TxRqst` bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

16.4.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the CPU has cleared it.

The Status Interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. A message interrupt is cleared by clearing the message object's `IntPnd` bit. The Status Interrupt is cleared by reading the **CAN Status (CANSTS)** register.

The interrupt identifier `IntId` in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register holds the value to 0. If the value of **CANINT** is different from 0, then there is an interrupt pending. If the `IE` bit is set in the **CANCTL** register, the interrupt line to the CPU is active. The interrupt line remains active until **CANINT** is 0, all interrupt sources have been cleared (the cause of the interrupt is reset), or until `IE` is reset, which disables interrupts from the CAN controller.

The value 0x8000 in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register (Error Interrupt or Status Interrupt). This indicates that there is either a new Error Interrupt or a new Status Interrupt. A write access can clear the `RxOK`, `TxOK`, and `LEC` flags in the **CANSTS** register, however, only a read access to the **CANSTS** register will clear the source of the Status Interrupt.

`IntId` points to the pending message interrupt with the highest interrupt priority. The `SIE` bit in the **CANCTL** register controls whether a change of the status register may cause an interrupt. The `EIE` bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the microcontroller's interrupt controller. The **CANINT** interrupt register is updated even when the `IE` bit is set to zero.

There are two possibilities when handling the source of a message interrupt. The first is to read the `IntId` bit in the **CANINT** interrupt register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and reset the message object's `IntPnd` at the same time by setting the `ClrIntPnd` bit in the **CAN IFn Command Mask (CANIFnCMSK)** register. When the `IntPnd` bit is cleared, the **CANINT** register will contain the message number for the next message object with a pending interrupt.

16.4.13 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

16.4.14 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 16-2 on page 476): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 16-3 on page 476). The length of the time quantum (t_q), which is the basic time unit of the bit time, is defined by the CAN controller's system clock (f_{sys}) and the Baud Rate Prescaler (`BRP`):

$$t_q = BRP / f_{sys}$$

The CAN module's system clock f_{sys} is the frequency of its CAN module clock input.

The Synchronization Segment `Sync_Seg` is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of `Sync_Seg` and the `Sync_Seg` is called the *phase error* of that edge.

The Propagation Time Segment `Prop_Seg` is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments `Phase_Seg1` and `Phase_Seg2` surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 16-2. CAN Bit Time

Table 16-3. CAN Protocol Ranges^a

Parameter	Range	Remark
BRP	[1 .. 32]	Defines the length of the time quantum t _q
Sync_Seg	1 t _q	Fixed length, synchronization of bus input to system clock
Prop_Seg	[1 .. 8] t _q	Compensates for the physical delay times
Phase_Seg1	[1 .. 8] t _q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 .. 8] t _q	May be shortened temporarily by synchronization
SJW	[1 .. 4] t _q	May not be longer than either Phase Buffer Segment

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, and SJW and BRP are combined in the other byte.

In these bit timing registers, the four components TSEG1, TSEG2, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits. Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] \times t_q$$

The data in the bit timing registers are the configuration input of the CAN protocol controller. The Baud Rate Prescaler (configured by BRP) defines the length of the time quantum, the basic time unit of the bit time; the Bit Timing Logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the Sample Point and processes the sampled bus input bit. The time after the Sample Point that is needed to calculate the next bit to be sent (that is, the data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT).

The IPT is application-specific but may not be longer than $2 t_q$; the CAN's IPT is $0 t_q$. Its length is the lower limit of the programmed length of `Phase_Seg2`. In case of synchronization, `Phase_Seg2` may be shortened to a value less than IPT, which does not affect bus timing.

16.4.15 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is the `Prop_Seg`. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for `Prop_Seg` is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The `Sync_Seg` is $1 t_q$ long (fixed), which leaves $(\text{bit time} - \text{Prop_Seg} - 1) t_q$ for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, that is, `Phase_Seg2 = Phase_Seg1`, else `Phase_Seg2 = Phase_Seg1 + 1`.

The minimum nominal length of `Phase_Seg2` has to be regarded as well. `Phase_Seg2` may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of $[0..2] t_q$.

The length of the Synchronization Jump Width is set to its maximum value, which is the minimum of 4 and `Phase_Seg1`.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- `df` = Maximum tolerance of oscillator frequency
- `fosc` = Actual oscillator frequency
- `fnom` = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq (\text{Phase_Seg1}, \text{Phase_Seg2})_{\min} / 2 \times (13 \times t_{\text{bit}} - \text{Phase_Seg2})$$

$$df_{\max} = 2 \times df \times f_{nom}$$

where:

- `Phase_Seg1` and `Phase_Seg2` are from Table 16-3 on page 476

- t_{bit} = Bit Time
- df_{max} = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

The resulting configuration is written into the **CAN Bit Timing (CANBIT)** register :

$(Phase_Seg2-1) \& (Phase_Seg1+Prop_Seg-1) \& (SynchronizationJumpWidth-1) \& (Prescaler-1)$

16.4.15.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, BRP is 0, and the bit rate is 1 Mbps.

```

 $t_q$  40 ns = 1/((BRP + 1) × CAN Clock)
delay of bus driver 50 ns
delay of receiver circuit 30 ns
delay of bus line (40m) 220 ns
 $t_{Prop}$  640 ns = 16 ×  $t_q$ 
 $t_{SJW}$  160 ns = 4 ×  $t_q$ 
 $t_{TSeg1}$  800 ns =  $t_{Prop}$  +  $t_{SJW}$ 
 $t_{TSeg2}$  160 ns = Information Processing Time + 4 ×  $t_q$ 
 $t_{Sync-Seg}$  40 ns = 1 ×  $t_q$ 
bit time 1000 ns =  $t_{Sync-Seg}$  +  $t_{TSeg1}$  +  $t_{TSeg2}$ 
tolerance for CAN_CLK 0.39 % =
    min(PB1,PB2)/ 2 × (13 × bit time - PB2) =
    0.1us/ 2 × (13× 1us - 2us)
    
```

In the above example, the parameters for the **CANBIT** register are: TSeg2=3, TSeg1=15, SJW =3 and BRP=0. This makes the final value programmed into the **CANBIT** register, 0x3FC0.

16.4.15.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of CAN clock is 50 MHz, BRP is 25, and the bit rate is 100 Kbps.

```

 $t_q$  500 ns = 1/((BRP + 1) × CAN clock)
delay of bus driver 200 ns
delay of receiver circuit 80 ns
delay of bus line (40m) 220 ns
 $t_{Prop}$  4.5 ms = 9 ×  $t_q$ 
 $t_{SJW}$  2 ms = 4 ×  $t_q$ 
 $t_{TSeg1}$  6.5 ms =  $t_{Prop}$  +  $t_{SJW}$ 
 $t_{TSeg2}$  3 ms = Information Processing Time + 6 ×  $t_q$ 
 $t_{Sync-Seg}$  500 ns = 1 ×  $t_q$ 
bit time 10 ms =  $t_{Sync-Seg}$  +  $t_{TSeg1}$  +  $t_{TSeg2}$ 
    
```

$$\begin{aligned} \text{tolerance for CAN_CLK } 1.58 \% = \\ \min(\text{PB1}, \text{PB2}) / 2 \times (13 \times \text{bit time} - \text{PB2}) = \\ 4\mu\text{s} / 2 \times (13 \times 10\mu\text{s} - 4\mu\text{s}) \end{aligned}$$

In this example, the concatenated bit time parameters are (4-1)3&(5-1)4&(4-1)2&(2-1)6, and **CANBIT** is programmed to 0x34C1.

In the above example, the parameters for the **CANBIT** register are: TSeg2=5, TSeg1=12, SJW =3 and BRP=24. This makes the final value programmed into the **CANBIT** register, 0x5CD8.

16.5 Controller Area Network Register Map

Table 16-4 on page 479 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000

16.6 Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or resetting `INIT`. If the device goes bus-off, it sets `INIT`, stopping all bus activities. Once `INIT` has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 * 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after `INIT` is reset, each time a sequence of 11 High bits has been monitored, a `Bit0Error` code is written to the **CANSTS** status register, enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

CAN Control (CANCTL)

CAN0 base: 0x4004.0000
Offset 0x000

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7	Test	R/W	0	Test Mode Enable 0: Normal Operation 1: Test Mode
6	CCE	R/W	0	Configuration Change Enable 0: Do not allow write access to the CANBIT register. 1: Allow write access to the CANBIT register if the <code>INIT</code> bit is 1.
5	DAR	R/W	0	Disable Automatic Retransmission 0: Auto retransmission of disturbed messages is enabled. 1: Auto retransmission is disabled.
4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	EIE	R/W	0	Error Interrupt Enable 0: Disabled. No Error Status interrupt is generated. 1: Enabled. A change in the <code>Boff</code> or <code>EWarn</code> bits in the CANSTS register generates an interrupt.

Bit/Field	Name	Type	Reset	Description
2	SIE	R/W	0	Status Interrupt Enable 0: Disabled. No Status interrupt is generated. 1: Enabled. An interrupt is generated when a message has successfully been transmitted or received, or a CAN bus error has been detected. A change in the TxOK , RxOK or LEC bits in the CANSTS register generates an interrupt.
1	IE	R/W	0	CAN Interrupt Enable 0: Interrupts disabled. 1: Interrupts enabled.
0	INIT	R/W	1	Initialization 0: Normal operation. 1: Initialization started.

Register 2: CAN Status (CANSTS), offset 0x004

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared to 0 when a message has been transferred (reception or transmission) without error. The unused error code 7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An Error Interrupt is generated by the BOff and EWarn bits and a Status Interrupt is generated by the RxOK, TxOK, and LEC bits, assuming that the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPass bit or a write to the RxOK, TxOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

CAN Status (CANSTS)

CAN0 base: 0x4004.0000
Offset 0x004
Type R/W, reset 0x0000.0000

This enables the CPU to monitor the proceeding of the bus-off recovery sequence without any disturbances to the bus.</p> <p>0x6 CRC Error</p> <p>The CRC checksum was incorrect in the received message, indicating that the calculated value received did not match the calculated CRC of the data.</p> <p>0x7 Unused</p> <p>When the LEC bit shows this value, no CAN bus event was detected since the CPU wrote this value to LEC.</p>

Register 3: CAN Error Counter (CANERR), offset 0x008

This register contains the error counter values, which can be used to analyze the cause of an error.

CAN Error Counter (CANERR)

CAN0 base: 0x4004.0000

Offset 0x008

Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15	RP	RO	0	Received Error Passive 0: The Receive Error counter is below the Error Passive level (127 or less). 1: The Receive Error counter has reached the Error Passive level (128 or greater).
14:8	REC	RO	0x0	Receive Error Counter State of the receiver error counter (0 to 127).
7:0	TEC	RO	0x0	Transmit Error Counter State of the transmit error counter (0 to 255).

Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are to be programmed to the system clock frequency. This register is write-enabled by the `CCE` and `INIT` bits in the `CANCTL` register. See “Bit Time and Bit Rate” on page 475 for more information.

CAN Bit Timing (CANBIT)

CAN0 base: 0x4004.0000
Offset 0x00C
Type R/W, reset 0x0000.2301

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	reserved	TSeg2		TSeg1				SJW		BRP						
Type	RO	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Reset	0	0	1	0	0	0	1	1	0	0	0	0	0	0	0	1

Bit/Field	Name	Type	Reset	Description
31:15	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
14:12	TSeg2	R/W	0x2	Time Segment after Sample Point 0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. So, for example, a reset value of 0x2 defines that there is 3(2+1) bit time quanta defined for <code>Phase_Seg2</code> (see Figure 16-2 on page 476). The bit time quanta is defined by <code>BRP</code> .
11:8	TSeg1	R/W	0x3	Time Segment Before Sample Point 0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. So, for example, the reset value of 0x3 defines that there is 4(3+1) bit time quanta defined for <code>Phase_Seg1</code> (see Figure 16-2 on page 476). The bit time quanta is define by <code>BRP</code> .
7:6	SJW	R/W	0x0	(Re)Synchronization Jump Width 0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used. During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of <code>TSeg2</code> or <code>TSeg1</code> by the value in <code>SJW</code> . So the reset value of 0 adjusts the length by 1 bit time quanta.

Bit/Field	Name	Type	Reset	Description
5:0	BRP	R/W	0x1	<p>Baud Rate Prescaler</p> <p>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.</p> <p>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p> <p>BRP defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).</p> <p>The CANBRPE register can be used to further divide the bit time.</p>

Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the CPU has cleared it. If the `IntId` bit is not 0x0000 (the default) and the `IE` bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the `IntId` bit is set back to 0x0000 when the cause of all interrupts are reset, or until `IE` is reset.

Note: Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

CAN Interrupt (CANINT)

CAN0 base: 0x4004.0000

Offset 0x010

15:0	IntId	RO	0x0000	Interrupt Identifier

The number in this field indicates the source of the interrupt.

Value	Definition
0x0000	No interrupt pending
0x0001-0x0020	Number of the message object that caused the interrupt
0x0021-0x7FFF	Unused
0x8000	Status Interrupt
0x8001-0xFFFF	Unused

Register 6: CAN Test (CANTST), offset 0x014

This is the test mode register for self-test and external pin access. It is write-enabled by the `Test` bit in the `CANCTL` register. Different test functions may be combined, however, CAN transfers will be affected if the `Tx` bits in this register are not zero.

CAN Test (CANTST)

CAN0 base: 0x4004.0000
 Offset 0x014
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description

Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020**Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

This register is used to start a transfer when its MNUM bit field is updated. Its Busy bit indicates that the information is transferring from the CAN Interface Registers to the internal message RAM.

A message transfer is started as soon as there is a write of the message object number with the MNUM bit. With this write operation, the Busy bit is automatically set to 1 to indicate that a transfer is in progress. After a wait time of 3 to 6 CAN_CLK periods, the transfer between the interface register and the message RAM completes, which then sets the Busy bit back to 0.

CAN IF1 Command Request (CANIF1CRQ)

Register 22: CAN IF1 Data A1 (CANIF1DA1), offset 0x03C

Register 23: CAN IF1 Data A2 (CANIF1DA2), offset 0x040

Register 24: CAN IF1 Data B1 (CANIF1DB1), offset 0x044

Register 25: CAN IF1 Data B2 (CANIF1DB2), offset 0x048

Register 26: CAN IF2 Data A1 (CANIF2DA1), offset 0x09C

Register 27: CAN IF2 Data A2 (CANIF2DA2), offset 0x0A0

Register 28: CAN IF2 Data B1 (CANIF2DB1), offset 0x0A4

Register 29: CAN IF2 Data B2 (CANIF2DB2), offset 0x0A8

These registers contain the data to be sent or that has been received. In a CAN data frame, data byte 0 is the first byte to be transmitted or received and data byte 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte is transmitted first.

CAN IF1 Data A1 (CANIF1DA1)

CAN0 base: 0x4004.0000
 Offset 0x03C
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Data	R/W	0x00	Data

The **CANIFnDA1** registers contain data bytes 1 and 0; **CANIFnDA2** data bytes 3 and 2; **CANIFnDB1** data bytes 5 and 4; and **CANIFnDB2** data bytes 7 and 6.

Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100**Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104**

The **CANTXRQ1** and **CANTXRQ2** registers hold the `TxRqst` bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The `TxRqst` bit of a specific message object can be changed by three sources: (1) the CPU via the **CAN IFn Message Control (CANIFnMCTL)** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the `TxRqst` bit of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the `TxRqst` bit of the second 16 message objects.

CAN Transmission Request 1 (CANTXRQ1)

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	TxRqst	RO	0x00	Transmission Request Bits (of all message objects) 0: The message object is not waiting for transmission. 1: The transmission of the message object is requested and is not yet done.

Register 32: CAN New Data 1 (CANNWDA1), offset 0x120

Register 33: CAN New Data 2 (CANNWDA2), offset 0x124

The **CANNWDA1** and **CANNWDA2** registers hold the *NewDat* bits of the 32 message objects. By reading these bits, the CPU can check which message object has its data portion updated. The *NewDat* bit of a specific message object can be changed by three sources: (1) the CPU via the **CAN IFn Message Control (CANIFnMCTL)** register, (2) the message handler state machine after the reception of a data frame, or (3) the message handler state machine after a successful transmission.

The **CANNWDA1** register contains the *NewDat* bit of the first 16 message objects in the message RAM; the **CANNWDA2** register contains the *NewDat* bit of the second 16 message objects.

CAN New Data 1 (CANNWDA1)

CAN0 base: 0x4004.0000

15:0	NewDat	RO	0x00	New Data Bits (of all message objects) 0: No new data has been written into the data portion of this message object by the message handler since the last time this flag was cleared by the CPU. 1: The message handler or the CPU has written new data into the data portion of this message object.

Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140**Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144**

The **CANMSG1INT** and **CANMSG2INT** registers hold the `IntPnd` bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The `IntPnd` bit of a specific message object can be changed through two sources: (1) the CPU via the **CAN IFn Message Control (CANIFnMCTL)** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CAN Interrupt (CANINT)** register.

The **CANMSG1INT** register contains the `IntPnd` bit of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the `IntPnd` bit of the second 16 message objects.

CAN Message 1 Interrupt Pending (CANMSG1INT)

15:0	MsgVal	RO	0x00	Message Valid Bits (of all message objects) 0: This message object is not configured and is ignored by the message handler. 1: This message object is configured and should be considered by the message handler.

17 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages, and provides a logical output that signals the comparison result.

The LM3S2671 controller provides three independent integrated analog comparators that can be configured to drive an output or generate an interrupt or ADC event.

Note: Not all comparators have the option to drive an output pin. See the Comparator Operating Mode tables in “Functional Description” on page 510 for more information.

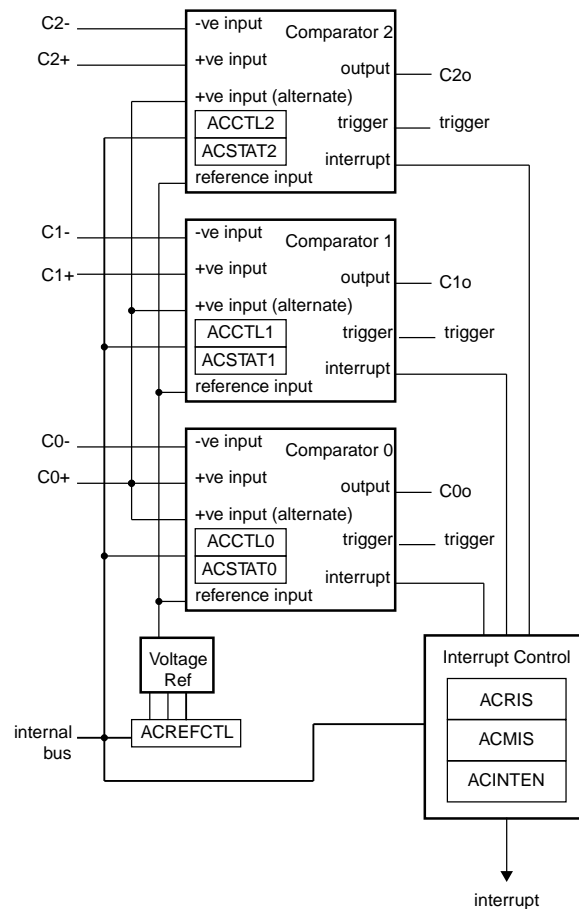

A comparator can compare a test voltage against any one of these voltages:

- An individual external reference voltage
- A shared single external reference voltage
- A shared internal reference voltage

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board, or it can be used to signal the application via interrupts or triggers to the ADC to cause it to start capturing a sample sequence. The interrupt generation and ADC triggering logic is separate. This means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

17.1 Block Diagram

Figure 17-1. Analog Comparator Module Block Diagram

17.2 Functional Description

Important: It is recommended that the Digital-Input enable (the `GPIOEN` bit in the GPIO module) for the analog input pin be disabled to prevent excessive current draw from the I/O pads.

The comparator compares the V_{IN-} and V_{IN+} inputs to produce an output, V_{OUT} .

$$V_{IN-} < V_{IN+}, V_{OUT} = 1$$

$$V_{IN-} > V_{IN+}, V_{OUT} = 0$$

As shown in Figure 17-2 on page 511, the input source for V_{IN-} is an external input. In addition to an external input, input sources for V_{IN+} can be the +ve input of comparator 0 or an internal reference.

Figure 17-2. Structure of Comparator Unit

A comparator is configured through two status/control registers (**ACCTL** and **ACSTAT**). The internal reference is configured through one control register (**ACREFCTL**). Interrupt status and control is configured through three registers (**ACMIS**, **ACRIS**, and **ACINTEN**). The operating modes of the comparators are shown in the Comparator Operating Mode tables.

Typically, the comparator output is used internally to generate controller interrupts. It may also be used to drive an external pin or generate an analog-to-digital converter (ADC) trigger.

Important: Certain register bit values must be set before using the analog comparators. The proper pad configuration for the comparator input and output pins are described in the Comparator Operating Mode tables.

Table 17-1. Comparator 0 Operating Modes

ACCNTL0 Comparator 0					
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger
00	C0-	C0+	C0o	yes	yes
01	C0-	C0+	C0o	yes	yes
10	C0-	Vref	C0o	yes	yes
11	C0-	reserved	C0o	yes	yes

Table 17-2. Comparator 1 Operating Modes

ACCNTL1 Comparator 1					
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger
00	C1-	C1o/C1+ ^a	C1o/C1+	yes	yes
01	C1-	C0+	C1o/C1+	yes	yes
10	C1-	Vref	C1o/C1+	yes	yes
11	C1-	reserved	C1o/C1+	yes	yes

a. C1o and C1+ signals share a single pin and may only be used as one or the other.

Table 17-3. Comparator 2 Operating Modes

ACCNTL2	Comparator 2				
ASRCP	VIN-	VIN+	Output	Interrupt	ADC Trigger
00	C2-	C2o/C2+ ^a	C2o/C2+	yes	yes
01	C2-	C0+	C2o/C2+	yes	yes
10	C2-	Vref	C2o/C2+	yes	yes
11	C2-	reserved	C2o/C2+	yes	yes

a. C2o and C2+ signals share a single pin and may only be used as one or the other.

17.2.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 17-3 on page 512. This is controlled by a single configuration register (**ACREFCTL**). Table 17-4 on page 512 shows the programming options to develop specific internal reference values, to compare an external voltage against a particular voltage generated internally.

Figure 17-3. Comparator Internal Reference Structure

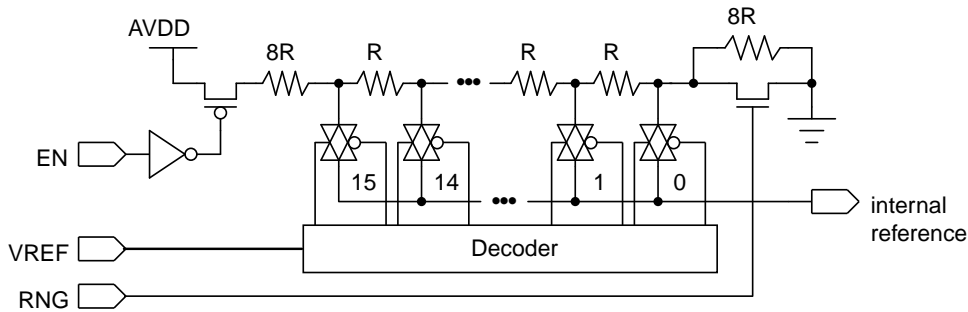

Table 17-4. Internal Reference Voltage and ACREFTL Field Values

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=0	RNG=X	0 V (GND) for any value of VREF; however, it is recommended that RNG=1 and VREF=0 for the least noisy ground reference.

ACREFCTL Register		Output Reference Voltage Based on VREF Field Value
EN Bit Value	RNG Bit Value	
EN=1	RNG=0	<p>Total resistance in ladder is 31 R.</p> $V_{REF} = AV_{DD} \times \frac{RV_{REF}}{R_T}$ $V_{REF} = AV_{DD} \times \frac{(V_{REF} + 8)}{31}$ $V_{REF} = 0.85 + 0.106 \times V_{REF}$ <p>The range of internal reference in this mode is 0.85-2.448 V.</p>
	RNG=1	<p>Total resistance in ladder is 23 R.</p> $V_{REF} = AV_{DD} \times \frac{RV_{REF}}{R_T}$ $V_{REF} = AV_{DD} \times \frac{V_{REF}}{23}$ $V_{REF} = 0.143 \times V_{REF}$ <p>The range of internal reference for this mode is 0-2.152 V.</p>

17.3 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator 0 clock by writing a value of 0x0010.0000 to the **RCGC1** register in the System Control module.
2. In the GPIO module, enable the GPIO port/pin associated with C0- as a GPIO input.
3. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
4. Configure comparator 0 to use the internal voltage reference and to *not* invert the output on the C0o pin by writing the **ACCTL0** register with the value of 0x0000.040C.
5. Delay for some time.
6. Read the comparator output value by reading the **ACSTAT0** register's OVAL value.

Change the level of the signal input on C0- to see the OVAL value change.

17.4 Register Map

Table 17-5 on page 514 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000.

Table 17-5. Analog Comparators Register Map

Offset	Name	Type	Reset	Description	See page

18 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The Stellaris[®] PWM module consists of one PWM generator block and a control block. The PWM generator block contains one timer (16-bit down or up/down counter), two PWM comparators, a PWM signal generator, a dead-band generator, and an interrupt/ADC-trigger selector. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

The PWM generator block produces two PWM signals that can either be independent signals (other than being based on the same timer and therefore having the same frequency) or a single pair of complementary signals with dead-band delays inserted. The output of the PWM generation block is managed by the output control block before being passed to the device pins.

The Stellaris[®] PWM module provides a great deal of flexibility. It can generate simple PWM signals, such as those required by a simple charge pump. It can also generate paired PWM signals with dead-band delays, such as those required by a half-H bridge driver.

18.1 Block Diagram

Figure 18-1 on page 522 provides the Stellaris[®] PWM module unit diagram and Figure 18-2 on page 523 provides a more detailed diagram of a Stellaris[®] PWM generator. The LM3S2671 controller contains one generator block (PWM0) and generates two independent PWM signals or one paired PWM signal with dead-band delays inserted.

Figure 18-1. PWM Unit Diagram

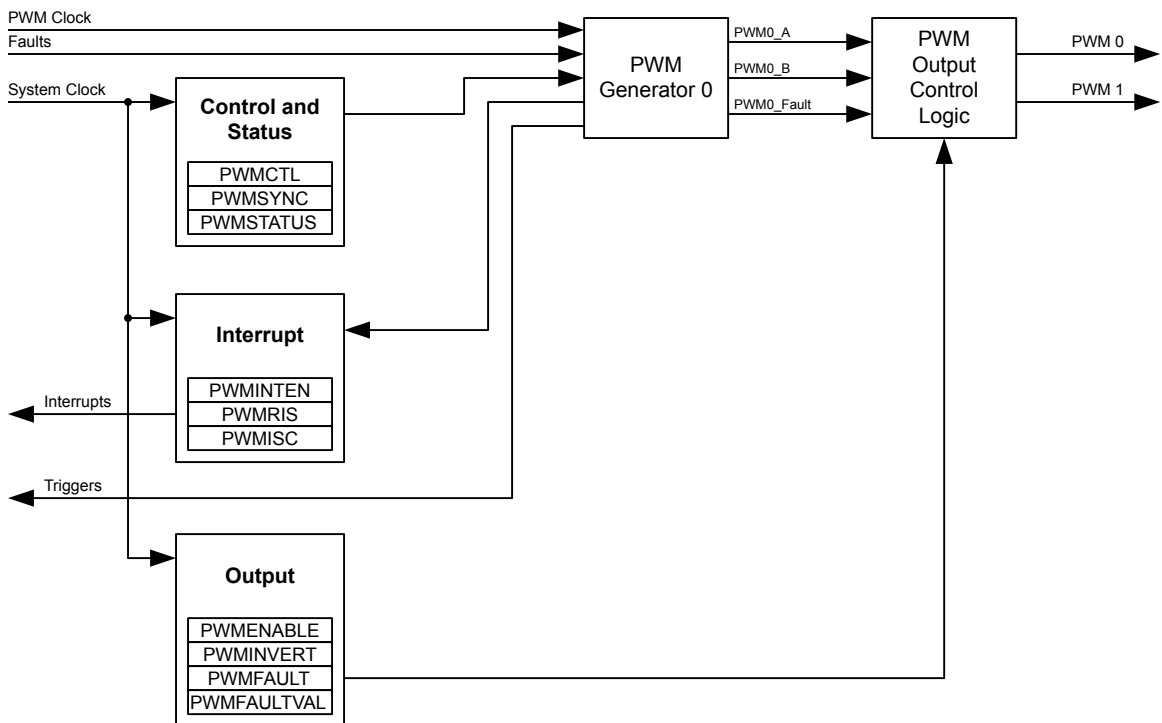

Figure 18-2. PWM Module Block Diagram

18.2 Functional Description

18.2.1 PWM Timer

The timer runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse.

18.2.2 PWM Comparators

There are two comparators in the PWM generator that monitor the value of the counter; when either match the counter, they output a single-clock-cycle-width High pulse. When in Count-Up/Down mode, these comparators match both when counting up and when counting down; they are therefore qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 18-3 on page 524 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 18-4 on page 524 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode.

Figure 18-3. PWM Count-Down Mode

Figure 18-4. PWM Count-Up/Down Mode

18.2.3 PWM Signal Generator

The PWM generator takes these pulses (qualified by the direction signal), and generates two PWM signals. In Count-Down mode, there are four events that can affect the PWM signal: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect the PWM signal: zero, load, match A down, match A up, match B down, and match B up. The match

A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, $PWMA$, is generated based only on the match A event, and the second signal, $PWMB$, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 18-5 on page 525 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles.

Figure 18-5. PWM Generation Example In Count-Up/Down Mode

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the $PWMA$ signal, and changing the value of comparator B changes the duty cycle of the $PWMB$ signal.

18.2.4 Dead-Band Generator

The two PWM signals produced by the PWM generator are passed to the dead-band generator. If disabled, the PWM signals simply pass through unmodified. If enabled, the second PWM signal is lost and two PWM signals are generated based on the first PWM signal. The first output PWM signal is the input signal with the rising edge delayed by a programmable amount. The second output PWM signal is the inversion of the input signal with a programmable delay added between the falling edge of the input signal and the rising edge of this new signal.

This is therefore a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 18-6 on page 525 shows the effect of the dead-band generator on an input PWM signal.

Figure 18-6. PWM Dead-Band Generator

18.2.5 Interrupt/ADC-Trigger Selector

The PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position within the PWM signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

18.2.6 Synchronization Methods

The PWM unit provides one PWM generators providing two PWM outputs that may be used in a wide variety of applications. Generally speaking, this falls into combinations of two categories of operation:

- **Unsynchronized:** The PWM generator and its two output signals are used by itself, independent of other PWM generators.
- **Synchronized:** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base.

If multiple PWM generators are configured with the same counter load value, this can be used to guarantee that they also have the same count value (this does imply that the PWM generators must be configured before they are synchronized). With this, more than two PWM signals can be produced with a known relationship between the edges of those signals since the counters always have the same values. Other states in the unit provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM unit generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the `Sync` bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary `Sync` bits in one access. For example, setting the `Sync0` and `Sync1` bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additionally, the state of a PWM unit is affected by writing to the registers of the PWM unit and the PWM units' generators, which has an effect on the synchronization between multiple PWM generators. Depending on the register accessed, the register state is updated in one of the following three ways:

- **Immediately:** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized:** The write value does not affect the logic until the counter reaches the value zero. In this case, the effect of the write is deferred until the end of the PWM cycle (when the counter reaches zero). By waiting for the counter to reach zero, a guaranteed behavior is defined, and overly short or overly long output PWM pulses are prevented.
- **Globally Synchronized:** The write value does not affect the logic until two sequential events have occurred: (1) the global synchronization bit applicable to the generator is set, and (2) the counter reaches zero. In this case, the effect of the write is deferred until the end of the PWM cycle (when the counter reaches zero) following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism

across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of the **PWMnCTL** register `Update` bit value:

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect. The default update mode is immediate.

- Module-Level Register: **PWMENABLE**
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL**.

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization, and therefore, do not need synchronous update functionality.

18.2.7 Fault Conditions

There are two external conditions that affect the PWM block; the signal input on the Fault pin and the stalling of the controller by a debugger. There are two mechanisms available to handle such conditions: the output signals can be forced into an inactive state and/or the PWM timers can be stopped.

Each output signal has a fault bit. If set, a fault input signal causes the corresponding output signal to go into the inactive state. If the inactive state is a safe condition for the signal to be in for an extended period of time, this keeps the output signal from driving the outside world in a dangerous manner during the fault condition. A fault condition can also generate a controller interrupt.

Each PWM generator can also be configured to stop counting during a stall condition. The user can select for the counters to run until they reach zero then stop, or to continue counting and reloading. A stall condition does not generate a controller interrupt.

18.2.8 Output Control Block

With the PWM generator block producing two raw PWM signals, the output control block takes care of the final conditioning of the PWM signals before they go to the pins. Via a single register, the set of PWM signals that are actually enabled to the pins can be modified; this can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). Similarly, fault control can disable any of the PWM signals as well. A final inversion can be applied to any of the PWM signals, making them active Low instead of the default active High.

18.3 Initialization and Configuration

The following example shows how to initialize the PWM Generator 0 with a 25-KHz frequency, and with a 25% duty cycle on the `PWM0` pin and a 75% duty cycle on the `PWM1` pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by writing a value of `0x0010.0000` to the **RCGC0** register in the System Control module.

2. Enable the clock to the appropriate GPIO module via the **RCGC2** register in the System Control module.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register.
4. Configure the **Run-Mode Clock Configuration (RCC)** register in the System Control module to use the PWM divide (**USEPWMDIV**) and set the divider (**PWMDIV**) to divide by 2 (000).
5. Configure the PWM generator for countdown mode with immediate updates to the parameters.
 - Write the **PWM0CTL** register with a value of 0x0000.0000.
 - Write the **PWM0GENA** register with a value of 0x0000.008C.
 - Write the **PWM0GENB** register with a value of 0x0000.080C.
6. Set the period. For a 25-KHz frequency, the period = 1/25,000, or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. This translates to 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the **Load** field in the **PWM0LOAD** register to the requested period minus one.
 - Write the **PWM0LOAD** register with a value of 0x0000.018F.
7. Set the pulse width of the **PWM0** pin for a 25% duty cycle.
 - Write the **PWM0CMPA** register with a value of 0x0000.012B.
8. Set the pulse width of the **PWM1** pin for a 75% duty cycle.
 - Write the **PWM0CMPB** register with a value of 0x0000.0063.
9. Start the timers in PWM generator 0.
 - Write the **PWM0CTL** register with a value of 0x0000.0001.
10. Enable PWM outputs.
 - Write the **PWMENABLE** register with a value of 0x0000.0003.

18.4 Register Map

Table 18-1 on page 528 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM base address of 0x4002.8000.

Table 18-1. PWM Register Map

18.5 Register Descriptions

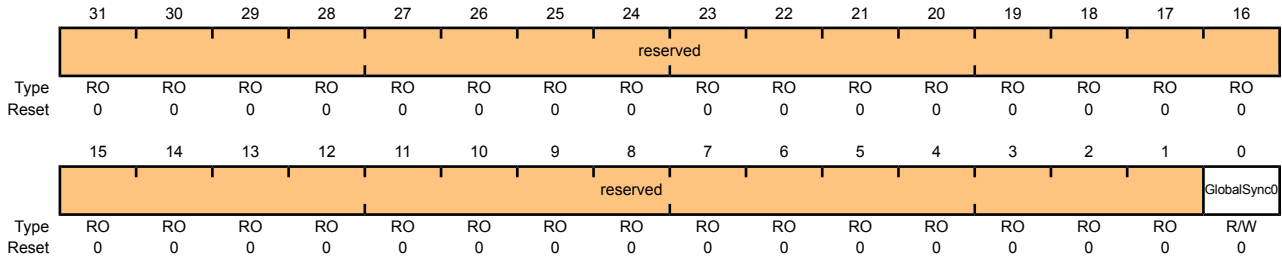

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

Register 1: PWM Master Control (PWMCTL), offset 0x000

This register provides master control over the PWM generation block.

PWM Master Control (PWMCTL)

Base 0x4002.8000
 Offset 0x000
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	GlobalSync0	R/W	0	Update PWM Generator 0 Setting this bit causes any queued update to a load or comparator register in PWM generator 0 to be applied the next time the corresponding counter becomes zero. This bit automatically clears when the updates have completed; it cannot be cleared by software.

Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Writing a bit in this register to 1 causes the specified counter to reset back to 0; writing multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

PWM Time Base Sync (PWMSYNC)

Base 0x4002.8000

Offset 0x004

Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO

	reserved															
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

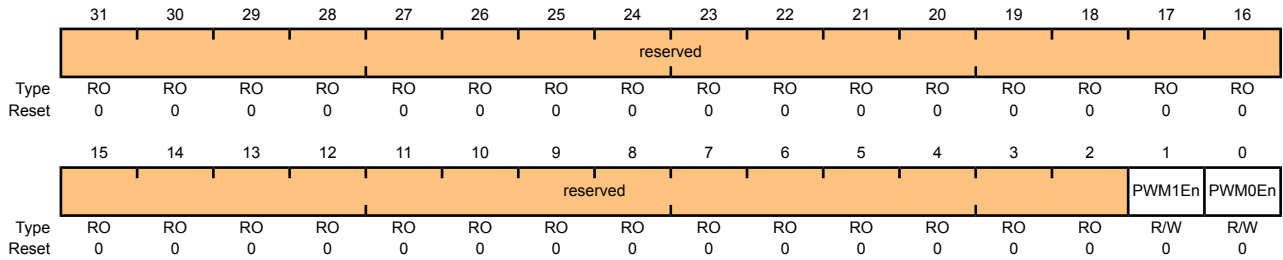

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	Sync0	R/W	0	Reset Generator 0 Counter Performs a reset of the PWM generator 0 counter.

Register 3: PWM Output Enable (PWMENABLE), offset 0x008

This register provides a master control of which generated PWM signals are output to device pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding PWM signal is passed through to the output stage, which is controlled by the **PWMINVERT** register. When bits are not set, the PWM signal is replaced by a zero value which is also passed to the output stage.

PWM Output Enable (PWMENABLE)

Base 0x4002.8000
 Offset 0x008
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PWM1En	R/W	0	PWM1 Output Enable When set, allows the generated PWM1 signal to be passed to the device pin.
0	PWM0En	R/W	0	PWM0 Output Enable When set, allows the generated PWM0 signal to be passed to the device pin.

Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the PWM signals on the device pins. The PWM signals generated by the PWM generator are active High; they can optionally be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive channels maintain the correct polarity.

PWM Output Inversion (PWMINVERT)

Base 0x4002.8000
Offset 0x00C
Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
	reserved																
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	reserved														PWM1Inv	PWM0Inv	
Type	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	RO	R/W	R/W
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	PWM1Inv	R/W	0	Invert PWM1 Signal When set, the generated PWM1 signal is inverted.
0	PWM0Inv	R/W	0	Invert PWM0 Signal When set, the generated PWM0 signal is inverted.

Register 5: PWM Output Fault (PWMFAULT), offset 0x010

This register controls the behavior of the PWM outputs in the presence of fault conditions. Both the fault inputs and debug events are considered fault conditions. On a fault condition, each PWM signal can be passed through unmodified or driven to a specified value. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the PWM signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

PWM Output Fault (PWMFAULT)

Base 0x4002.8000
 Offset 0x010
 Type R/W, reset 0x0000.0000

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	IntFault0	R/W	0	Interrupt Fault 0 When set, an interrupt occurs when the <code>FAULT0</code> input is asserted or the fault condition for PWM generator 0 is asserted.
15:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	IntPWM0	R/W	0	PWM0 Interrupt Enable When set, an interrupt occurs when the PWM generator 0 block asserts an interrupt.

Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller. The fault interrupt is latched on detection; it must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register (see page 537). The PWM generator interrupts simply reflect the status of the PWM generator; they are cleared via the interrupt status register in the PWM generator block. Bits set to 1 indicate the events that are active; zero bits indicate that the event in question is not active.

PWM Raw Interrupt Status (PWMRIS)

Base 0x4002.8000
 Offset 0x018
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	IntFault0	RO	0	Interrupt Fault PWM 0 Indicates that the <code>FAULT0</code> input is asserting or the fault condition for PWM generator 0 is asserting.
15:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	IntPWM0	RO	0	PWM0 Interrupt Asserted Indicates that the PWM generator 0 block is asserting its interrupt.

Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the PWM generator block. A bit set to 1 indicates that the generator block is asserting an interrupt. The individual interrupt status registers must be consulted to determine the reason for the interrupt, and used to clear the interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status.

Register 9: PWM Status (PWMSTATUS), offset 0x020

This register provides the status of the FAULT0 through FAULT3 input signals.

PWM Status (PWMSTATUS)

Base 0x4002.8000
 Offset 0x020
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	Fault0	RO	0	Fault0 Interrupt Status When set, indicates the FAULT0 input is asserted, or that the fault condition for PWM generator 0 is asserted.

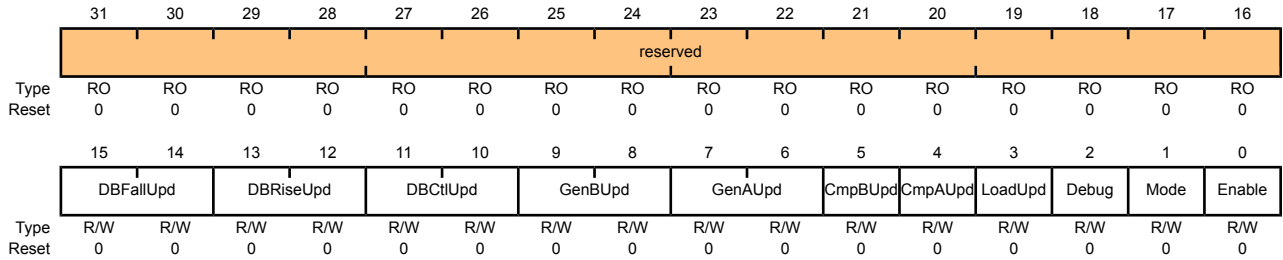

Register 10: PWM0 Control (PWM0CTL), offset 0x040

This register configures the PWM signal generation block. The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via this register. The block produces the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the `PWM0` and `PWM1` outputs.

PWM0 Control (PWM0CTL)

0	Enable	R/W	0	<p>PWM Block Enable</p> <p>Master enable for the PWM generation block. When not set, the entire block is disabled and not clocked. When set, the block is enabled and produces PWM signals.</p>

Register 11: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044

This register controls the interrupt and ADC trigger generation capabilities of the PWM generator. The events that can cause an interrupt or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the comparator A register while counting up
- The counter being equal to the comparator A register while counting down
- The counter being equal to the comparator B register while counting up
- The counter being equal to the comparator B register while counting down

Any combination of these events can generate either an interrupt, or an ADC trigger; though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified.

0	IntCntZero	R/W1C	0	Counter=0 Interrupt Indicates that the counter has matched 0.

Register 14: PWM0 Load (PWM0LOAD), offset 0x050

This register contains the load value for the PWM counter. Based on the counter mode, either this value is loaded into the counter after it reaches zero, or it is the limit of up-counting after which the counter decrements back to zero.

If the Load Value Update mode is immediate, this value is used the next time the counter reaches zero; if the mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

PWM0 Load (PWM0LOAD)

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Load	R/W	0	Counter Load Value The counter load value.

Register 15: PWM0 Counter (PWM0COUNT), offset 0x054

This register contains the current value of the PWM counter. When this value matches the load register, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers, see page 551 and page 554) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register, see page 543). A pulse with the same capabilities is generated when this value is zero.

PWM0 Counter (PWM0COUNT)

Base 0x4002.8000
 Offset 0x054
 Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	Count	RO	0x00	Counter Value The current value of the counter.

Register 16: PWM0 Compare A (PWM0CMPA), offset 0x058

This register contains a value to be compared against the counter. When this value matches the counter, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register (see page 547), then no pulse is ever output.

If the comparator A update mode is immediate (based on the **CompAUpd** bit in the **PWMnCTL** register), this 16-bit **CompA** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWM0 Compare A (PWM0CMPA)

Base 0x4002.8000
 Offset 0x058
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CompA	R/W	0x00	Comparator A Value The value to be compared against the counter.

Register 17: PWM0 Compare B (PWM0CMPB), offset 0x05C

This register contains a value to be compared against the counter. When this value matches the counter, a pulse is output; this can drive the generation of a PWM signal (via the **PWMnGENA/PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register, no pulse is ever output.

If the comparator B update mode is immediate (based on the `CompBUpd` bit in the **PWMnCTL** register), this 16-bit `CompB` value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWM0 Compare B (PWM0CMPB)

Base 0x4002.8000
 Offset 0x05C
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	CompB	R/W	0x00	Comparator B Value The value to be compared against the counter.

Register 18: PWM0 Generator A Control (PWM0GENA), offset 0x060

This register controls the generation of the PWM_nA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators. When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENA** register controls generation of the $PWM0A$ signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the $GenAUpd$ field encoding in the **PWMnCTL** register), this 16-bit $GenAUpd$ value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Register 19: PWM0 Generator B Control (PWM0GENB), offset 0x064

This register controls the generation of the PWM_{nB} signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators. When the counter is running in Down mode, only four of these events occur; when running in Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the PWM signal that is produced.

The **PWM0GENB** register controls generation of the PWM_{0B} signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the $GenBU_{pd}$ field encoding in the **PWMnCTL** register), this 16-bit $GenBU_{pd}$ value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

Register 20: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068

The **PWM0DBCTL** register controls the dead-band generator, which produces the **PWM0** and **PWM1** signals based on the **PWM0A** and **PWM0B** signals. When disabled, the **PWM0A** signal passes through to the **PWM0** signal and the **PWM0B** signal passes through to the **PWM1** signal. When enabled and inverting the resulting waveform, the **PWM0B** signal is ignored; the **PWM0** signal is generated by delaying the rising edge(s) of the **PWM0A** signal by the value in the **PWM0DBRISE** register (see page 558), and the **PWM1** signal is generated by delaying the falling edge(s) of the **PWM0A** signal by the value in the **PWM0DBFALL** register (see page 559).

If the Dead-Band Control mode is immediate (based on the **DBCTLUpd** field encoding in the **PWMnCTL** register), this 16-bit **DBCTLUpd** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWM0 Dead-Band Control (PWM0DBCTL)

31:1	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
0	Enable	R/W	0	Dead-Band Generator Enable When set, the dead-band generator inserts dead bands into the output signals; when clear, it simply passes the PWM signals through.

Register 21: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C

The **PWM0DBRISE** register contains the number of clock ticks to delay the rising edge of the **PWM0A** signal when generating the **PWM0** signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, the **PWM0DBRISE** register is ignored. If the value of this register is larger than the width of a High pulse on the input PWM signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the input High time always exceeds the rising-edge delay.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the **DBRIseUpd** field encoding in the **PWMnCTL** register), this 16-bit **DBRIseUpd** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE)

Base 0x4002.8000
 Offset 0x06C
 Type R/W, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	RiseDelay	R/W	0	Dead-Band Rise Delay The number of clock ticks to delay the rising edge.

Register 22: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070

The **PWM0DBFALL** register contains the number of clock ticks to delay the falling edge of the **PWM0A** signal when generating the **PWM1** signal. If the dead-band generator is disabled, this register is ignored. If the value of this register is larger than the width of a Low pulse on the input PWM signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the input Low time always exceeds the falling-edge delay.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the **DBFallUp** field encoding in the **PWMnCTL** register), this 16-bit **DBFallUp** value is used the next time the counter reaches zero. If the update mode is synchronous, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 530). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

20 Signal Tables

The following tables list the signals available for each pin. Functionality is enabled by software with the **GPIOAFSEL** register.

Important: All multiplexed pins are GPIOs by default, with the exception of the four JTAG pins (PC[3:0]) which default to the JTAG functionality.

Table 20-1 on page 561 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Table 20-2 on page 564 lists the signals in alphabetical order by signal name.

Table 20-3 on page 567 groups the signals by functionality, except for GPIOs. Table 20-4 on page 569 lists the GPIO pins and their alternate functionality.

Table 20-1. Signals by Pin Number

Pin Number	Pin Name	Pin Type	Buffer Type	Description
1	PE3	I/O	Analog	GPIO port E bit 3
	ADC0	I	Analog	ADC 0 input
2	PE2	I/O	Analog	GPIO port E bit 2
	ADC1	I	Analog	ADC 1 input
3	VDDA	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.
4	GNDA	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
5	PE1	I/O	Analog	GPIO port E bit 1
	ADC2	I	Analog	ADC 2 input
6	PE0	I/O	Analog	GPIO port E bit 0
	ADC3	I	Analog	ADC 3 input
7	LDO	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 μ F or greater. The LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
8	PE4	I/O	TTL	GPIO port E bit 4
	Fault0	I	TTL	FAULT 0
9	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
10	GND	-	Power	Ground reference for logic and I/O pins.
11	PC4	I/O	TTL	GPIO port C bit 4
12	VDD	-	Power	Positive supply for I/O and some logic.
13	GND	-	Power	Ground reference for logic and I/O pins.

Pin Number	Pin Name	Pin Type	Buffer Type	Description
14	PC5	I/O	TTL	GPIO port C bit 5
	C2-	I	Analog	Analog comparator 2 negative input
15	PC6	I/O	TTL	GPIO port C bit 6
	C2+	I	Analog	Analog comparator positive input
	C2o	O	TTL	Analog comparator 2 output
16	PC7	I/O	TTL	GPIO port C bit 7
	C1+	I	Analog	Analog comparator 1 plus input
	C1o	O	TTL	Comparator 1 output
17	PA0	I/O	TTL	GPIO port A bit 0
	U0Rx	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
18	PA1	I/O	TTL	GPIO port A bit 1
	U0Tx	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
19	PA2	I/O	TTL	GPIO port A bit 2
	SSI0Clk	I/O	TTL	SSI module 0 clock
20	PA3	I/O	TTL	GPIO port A bit 3
	SSI0Fss	I/O	TTL	SSI module 0 frame
21	PA4	I/O	TTL	GPIO port A bit 4
	SSI0Rx	I	TTL	SSI module 0 receive
22	PA5	I/O	TTL	GPIO port A bit 5
	SSI0Tx	O	TTL	SSI module 0 transmit
23	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
24	GND	-	Power	Ground reference for logic and I/O pins.
25	PA6	I/O	TTL	GPIO port A bit 6
	PWM0	O	TTL	PWM 0
26	PA7	I/O	TTL	GPIO port A bit 7
	PWM1	O	TTL	PWM 1
27	PB3	I/O	TTL	GPIO port B bit 3
	I2C0SDA	I/O	OD	I2C module 0 data
28	VDD	-	Power	Positive supply for I/O and some logic.
29	GND	-	Power	Ground reference for logic and I/O pins.
30	OSC0	I	Analog	Main oscillator crystal input or an external clock reference input.
31	OSC1	O	Analog	Main oscillator crystal output.
32	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
33	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
34	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
35	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.

Pin Number	Pin Name	Pin Type	Buffer Type	Description
36	GND	-	Power	Ground reference for logic and I/O pins.
37	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
38	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
39	GND	-	Power	Ground reference for logic and I/O pins.
40	$\overline{\text{RST}}$	I/O	TTL	System reset input.
41	PB0	I/O	TTL	GPIO port B bit 0
	CCP0	I/O	TTL	Capture/Compare/PWM 0
42	PB1	I/O	TTL	GPIO port B bit 1
	CCP1	I/O	TTL	Capture/Compare/PWM 1
43	VDD	-	Power	Positive supply for I/O and some logic.
44	GND	-	Power	Ground reference for logic and I/O pins.
45	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
46	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
47	PB2	I/O	TTL	GPIO port B bit 2
	I2C0SCL	I/O	OD	I2C module 0 clock
48	NC	-	-	No connect. Leave the pin electrically unconnected/isolated.
49	PC3	I/O	TTL	GPIO port C bit 3
	TDO	O	TTL	JTAG TDO and SWO
	SWO	O	TTL	JTAG TDO and SWO
50	PC2	I/O	TTL	GPIO port C bit 2
	TDI	I	TTL	JTAG TDI
51	PC1	I/O	TTL	GPIO port C bit 1
	TMS	I/O	TTL	JTAG TMS and SWDIO
	SWDIO	I/O	TTL	JTAG TMS and SWDIO
52	PC0	I/O	TTL	GPIO port C bit 0
	TCK	I	TTL	JTAG/SWD CLK
	SWCLK	I	TTL	JTAG/SWD CLK
53	GND	-	Power	Ground reference for logic and I/O pins.
54	VDD25	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
55	PB7	I/O	TTL	GPIO port B bit 7
	NMI	I	TTL	Non maskable interrupt
56	PB6	I/O	TTL	GPIO port B bit 6
	C0+	I	Analog	Analog comparator 0 positive input
	C0o	O	TTL	Analog comparator 0 output
57	PB5	I/O	TTL	GPIO port B bit 5
	C1-	I	Analog	Analog comparator 1 negative input

Pin Number	Pin Name	Pin Type	Buffer Type	Description
58	PB4	I/O	TTL	GPIO port B bit 4
	C0-	I	Analog	Analog comparator 0 negative input
59	VDD	-	Power	Positive supply for I/O and some logic.
60	GND	-	Power	Ground reference for logic and I/O pins.
61	PD0	I/O	Analog	GPIO port D bit 0
	CAN0Rx	I	Analog	CAN module 0 receive
62	PD1	I/O	Analog	GPIO port D bit 1
	CAN0Tx	O	Analog	CAN module 0 transmit
63	PD2	I/O	Analog	GPIO port D bit 2
64	PD3	I/O	Analog	GPIO port D bit 3

Table 20-2. Signals by Signal Name

Pin Name	Pin Number	Pin Type	Buffer Type	Description
ADC0	1	I	Analog	ADC 0 input
ADC1	2	I	Analog	ADC 1 input
ADC2	5	I	Analog	ADC 2 input
ADC3	6	I	Analog	ADC 3 input
C0+	56	I	Analog	Analog comparator 0 positive input
C0-	58	I	Analog	Analog comparator 0 negative input
C0o	56	O	TTL	Analog comparator 0 output
C1+	16	I	Analog	Analog comparator 1 plus input
C1-	57	I	Analog	Analog comparator 1 negative input
C1o	16	O	TTL	Comparator 1 output
C2+	15	I	Analog	Analog comparator positive input
C2-	14	I	Analog	Analog comparator 2 negative input
C2o	15	O	TTL	Analog comparator 2 output
CAN0Rx	61	I	Analog	CAN module 0 receive
CAN0Tx	62	O	Analog	CAN module 0 transmit
CCP0	41	I/O	TTL	Capture/Compare/PWM 0
CCP1	42	I/O	TTL	Capture/Compare/PWM 1
Fault0	8	I	TTL	FAULT 0
GND	10	-	Power	Ground reference for logic and I/O pins.
GND	13	-	Power	Ground reference for logic and I/O pins.
GND	24	-	Power	Ground reference for logic and I/O pins.
GND	29	-	Power	Ground reference for logic and I/O pins.
GND	36	-	Power	Ground reference for logic and I/O pins.
GND	39	-	Power	Ground reference for logic and I/O pins.
GND	44	-	Power	Ground reference for logic and I/O pins.
GND	53	-	Power	Ground reference for logic and I/O pins.
GND	60	-	Power	Ground reference for logic and I/O pins.

Pin Name	Pin Number	Pin Type	Buffer Type	Description
GNDA	4	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
I2C0SCL	47	I/O	OD	I2C module 0 clock
I2C0SDA	27	I/O	OD	I2C module 0 data
LDO	7	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 μ F or greater. The LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
NC	32	-	-	No connect. Leave the pin electrically unconnected/isolated.
NC	33	-	-	No connect. Leave the pin electrically unconnected/isolated.
NC	34	-	-	No connect. Leave the pin electrically unconnected/isolated.
NC	35	-	-	No connect. Leave the pin electrically unconnected/isolated.
NC	37	-	-	No connect. Leave the pin electrically unconnected/isolated.
NC	45	-	-	No connect. Leave the pin electrically unconnected/isolated.
NC	46	-	-	No connect. Leave the pin electrically unconnected/isolated.
NC	48	-	-	No connect. Leave the pin electrically unconnected/isolated.
NMI	55	I	TTL	Non maskable interrupt
OSC0	30	I	Analog	Main oscillator crystal input or an external clock reference input.
OSC1	31	O	Analog	Main oscillator crystal output.
PA0	17	I/O	TTL	GPIO port A bit 0
PA1	18	I/O	TTL	GPIO port A bit 1
PA2	19	I/O	TTL	GPIO port A bit 2
PA3	20	I/O	TTL	GPIO port A bit 3
PA4	21	I/O	TTL	GPIO port A bit 4
PA5	22	I/O	TTL	GPIO port A bit 5
PA6	25	I/O	TTL	GPIO port A bit 6
PA7	26	I/O	TTL	GPIO port A bit 7
PB0	41	I/O	TTL	GPIO port B bit 0
PB1	42	I/O	TTL	GPIO port B bit 1
PB2	47	I/O	TTL	GPIO port B bit 2
PB3	27	I/O	TTL	GPIO port B bit 3
PB4	58	I/O	TTL	GPIO port B bit 4
PB5	57	I/O	TTL	GPIO port B bit 5
PB6	56	I/O	TTL	GPIO port B bit 6

Pin Name	Pin Number	Pin Type	Buffer Type	Description
PB7	55	I/O	TTL	GPIO port B bit 7
PC0	52	I/O	TTL	GPIO port C bit 0
PC1	51	I/O	TTL	GPIO port C bit 1
PC2	50	I/O	TTL	GPIO port C bit 2
PC3	49	I/O	TTL	GPIO port C bit 3
PC4	11	I/O	TTL	GPIO port C bit 4
PC5	14	I/O	TTL	GPIO port C bit 5
PC6	15	I/O	TTL	GPIO port C bit 6
PC7	16	I/O	TTL	GPIO port C bit 7
PD0	61	I/O	Analog	GPIO port D bit 0
PD1	62	I/O	Analog	GPIO port D bit 1
PD2	63	I/O	Analog	GPIO port D bit 2
PD3	64	I/O	Analog	GPIO port D bit 3
PE0	6	I/O	Analog	GPIO port E bit 0
PE1	5	I/O	Analog	GPIO port E bit 1
PE2	2	I/O	Analog	GPIO port E bit 2
PE3	1	I/O	Analog	GPIO port E bit 3
PE4	8	I/O	TTL	GPIO port E bit 4
PWM0	25	O	TTL	PWM 0
PWM1	26	O	TTL	PWM 1
RST	40	I/O	TTL	System reset input.
SSI0Clk	19	I/O	TTL	SSI module 0 clock
SSI0Fss	20	I/O	TTL	SSI module 0 frame
SSI0Rx	21	I	TTL	SSI module 0 receive
SSI0Tx	22	O	TTL	SSI module 0 transmit
SWCLK	52	I	TTL	JTAG/SWD CLK
SWDIO	51	I/O	TTL	JTAG TMS and SWDIO
SWO	49	O	TTL	JTAG TDO and SWO
TCK	52	I	TTL	JTAG/SWD CLK
TDI	50	I	TTL	JTAG TDI
TDO	49	O	TTL	JTAG TDO and SWO
TMS	51	I/O	TTL	JTAG TMS and SWDIO
U0Rx	17	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.
U0Tx	18	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.
VDD	12	-	Power	Positive supply for I/O and some logic.
VDD	28	-	Power	Positive supply for I/O and some logic.
VDD	43	-	Power	Positive supply for I/O and some logic.
VDD	59	-	Power	Positive supply for I/O and some logic.
VDD25	9	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.

Pin Name	Pin Number	Pin Type	Buffer Type	Description
VDD25	23	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDD25	38	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDD25	54	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDDA	3	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.

Table 20-3. Signals by Function, Except for GPIO

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
ADC	ADC0	1	I	Analog	ADC 0 input
	ADC1	2	I	Analog	ADC 1 input
	ADC2	5	I	Analog	ADC 2 input
	ADC3	6	I	Analog	ADC 3 input
Analog Comparators	C0+	56	I	Analog	Analog comparator 0 positive input
	C0-	58	I	Analog	Analog comparator 0 negative input
	C0o	56	O	TTL	Analog comparator 0 output
	C1+	16	I	Analog	Analog comparator 1 plus input
	C1-	57	I	Analog	Analog comparator 1 negative input
	C1o	16	O	TTL	Comparator 1 output
	C2+	15	I	Analog	Analog comparator positive input
	C2-	14	I	Analog	Analog comparator 2 negative input
Controller Area Network	CAN0Rx	61	I	Analog	CAN module 0 receive
	CAN0Tx	62	O	Analog	CAN module 0 transmit
General-Purpose Timers	CCP0	41	I/O	TTL	Capture/Compare/PWM 0
	CCP1	42	I/O	TTL	Capture/Compare/PWM 1
I2C	I2C0SCL	47	I/O	OD	I2C module 0 clock
	I2C0SDA	27	I/O	OD	I2C module 0 data
JTAG/SWD/SWO	SWCLK	52	I	TTL	JTAG/SWD CLK
	SWDIO	51	I/O	TTL	JTAG TMS and SWDIO
	SWO	49	O	TTL	JTAG TDO and SWO
	TCK	52	I	TTL	JTAG/SWD CLK
	TDI	50	I	TTL	JTAG TDI
	TDO	49	O	TTL	JTAG TDO and SWO
	TMS	51	I/O	TTL	JTAG TMS and SWDIO
PWM	Fault0	8	I	TTL	FAULT 0
	PWM0	25	O	TTL	PWM 0

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
	PWM1	26	O	TTL	PWM 1
Power	GND	10	-	Power	Ground reference for logic and I/O pins.
	GND	13	-	Power	Ground reference for logic and I/O pins.
	GND	24	-	Power	Ground reference for logic and I/O pins.
	GND	29	-	Power	Ground reference for logic and I/O pins.
	GND	36	-	Power	Ground reference for logic and I/O pins.
	GND	39	-	Power	Ground reference for logic and I/O pins.
	GND	44	-	Power	Ground reference for logic and I/O pins.
	GND	53	-	Power	Ground reference for logic and I/O pins.
	GND	60	-	Power	Ground reference for logic and I/O pins.
	GND _A	4	-	Power	The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.
	LDO	7	-	Power	Low drop-out regulator output voltage. This pin requires an external capacitor between the pin and GND of 1 μ F or greater. The LDO pin must also be connected to the VDD25 pins at the board level in addition to the decoupling capacitor(s).
	VDD	12	-	Power	Positive supply for I/O and some logic.
	VDD	28	-	Power	Positive supply for I/O and some logic.
	VDD	43	-	Power	Positive supply for I/O and some logic.
	VDD	59	-	Power	Positive supply for I/O and some logic.
	VDD25	9	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
	VDD25	23	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
	VDD25	38	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
	VDD25	54	-	Power	Positive supply for most of the logic function, including the processor core and most peripherals.
VDD _A	3	-	Power	The positive supply (3.3 V) for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions.	
SSI	SSI0Clk	19	I/O	TTL	SSI module 0 clock
	SSI0Fss	20	I/O	TTL	SSI module 0 frame
	SSI0Rx	21	I	TTL	SSI module 0 receive
	SSI0Tx	22	O	TTL	SSI module 0 transmit
System Control & Clocks	NMI	55	I	TTL	Non maskable interrupt
	OSC0	30	I	Analog	Main oscillator crystal input or an external clock reference input.
	OSC1	31	O	Analog	Main oscillator crystal output.
	$\overline{\text{RST}}$	40	I/O	TTL	System reset input.
UART	U0Rx	17	I	TTL	UART module 0 receive. When in IrDA mode, this signal has IrDA modulation.

Function	Pin Name	Pin Number	Pin Type	Buffer Type	Description
	U0Tx	18	O	TTL	UART module 0 transmit. When in IrDA mode, this signal has IrDA modulation.

Table 20-4. GPIO Pins and Alternate Functions

GPIO Pin	Pin Number	Multiplexed Function	Multiplexed Function
PA0	17	U0Rx	
PA1	18	U0Tx	
PA2	19	SSI0Clk	
PA3	20	SSI0Fss	
PA4	21	SSI0Rx	
PA5	22	SSI0Tx

21 Operating Characteristics

Table 21-1. Temperature Characteristics

Characteristic ^a	Symbol	Value	Unit
Industrial operating temperature range	T_A	-40 to +85	°C

a. Maximum storage temperature is 150°C.

Table 21-2. Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal resistance (junction to ambient) ^a	Θ_{JA}	37	°C/W
Average junction temperature ^b	T_J	$T_A + (P_{AVG} \cdot \Theta_{JA})$	°C

a. Junction to ambient thermal resistance Θ_{JA} numbers are determined by a package simulator.

b. Power dissipation is a function of temperature.

22 Electrical Characteristics

22.1 DC Characteristics

22.1.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device.

Note: The device is not guaranteed to operate properly at the maximum ratings.

Table 22-1. Maximum Ratings

Characteristic ^a	Symbol	Value		Unit
		Min	Max	
I/O supply voltage (V_{DD})	V_{DD}	0	4	V
Core supply voltage (V_{DD25})	V_{DD25}	0	3	V
Analog supply voltage (V_{DDA})	V_{DDA}	0	4	V
Input voltage	V_{IN}	-0.3	5.5	V
Maximum current per output pins	I	-	25	mA

a. Voltages are measured with respect to GND.

Important: This device contains circuitry to protect the inputs against damage due to high-static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either GND or V_{DD}).

22.1.2 Recommended DC Operating Conditions

For special high-current applications, the GPIO output buffers may be used with the following restrictions. With the GPIO pins configured as 8-mA output drivers, a total of four GPIO outputs may be used to sink current loads up to 18 mA each. At 18-mA sink current loading, the V_{OL} value is specified as 1.2 V. The high-current GPIO package pins must be selected such that there are only a maximum of two per side of the physical package with the total number of high-current GPIO outputs not exceeding four for the entire package.

Table 22-2. Recommended DC Operating Conditions

Parameter	Parameter Name	Min	Nom	Max	Unit
V_{DD}	I/O supply voltage	3.0	3.3	3.6	V
V_{DD25}	Core supply voltage	2.25	2.5	2.75	V
V_{DDA}	Analog supply voltage	3.0	3.3	3.6	V
V_{IH}	High-level input voltage	2.0	-	5.0	V
V_{IL}	Low-level input voltage	-0.3	-	1.3	V
V_{SIH}	High-level input voltage for Schmitt trigger inputs	$0.8 * V_{DD}$	-	V_{DD}	V
V_{SIL}	Low-level input voltage for Schmitt trigger inputs	0	-	$0.2 * V_{DD}$	V
V_{OH}^a	High-level output voltage	2.4	-	-	V
V_{OL}^a	Low-level output voltage	-	-	0.4	V

Parameter	Parameter Name	Min	Nom	Max	Unit
I _{OH}	High-level source current, V _{OH} =2.4 V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA
I _{OL}	Low-level sink current, V _{OL} =0.4 V				
	2-mA Drive	2.0	-	-	mA
	4-mA Drive	4.0	-	-	mA
	8-mA Drive	8.0	-	-	mA

a. V_{OL} and V_{OH} shift to 1.2 V when using high-current GPIOs.

22.1.3 On-Chip Low Drop-Out (LDO) Regulator Characteristics

Table 22-3. LDO Regulator Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
V _{LDOOUT}	Programmable internal (logic) power supply output value	2.25	2.5	2.75	V
	Output voltage accuracy	-	2%	-	%
t _{PON}	Power-on time	-	-	100	μs
t _{ON}	Time on	-	-	200	μs
t _{OFF}	Time off	-	-	100	μs
V _{STEP}	Step programming incremental voltage	-	50	-	mV
C _{LDO}	External filter capacitor size for internal power supply	1.0	-	3.0	μF

22.1.4 Power Specifications

The power measurements specified in the tables that follow are run on the core processor using SRAM with the following specifications (except as noted):

- V_{DD} = 3.3 V
- V_{DD25} = 2.50 V
- V_{DDA} = 3.3 V
- Temperature = 25°C
- Clock Source (MOSC) = 3.579545 MHz Crystal Oscillator
- Main oscillator (MOSC) = enabled
- Internal oscillator (IOSC) = disabled

Table 22-4. Detailed Power Specifications

Parameter	Parameter Name	Conditions	3.3 V V_{DD} , V_{DDA} , V_{DDPHY}		2.5 V V_{DD25}		Unit
			Nom	Max	Nom	Max	
I_{DD_RUN}	Run mode 1 (Flash loop)	$V_{DD25} = 2.50\text{ V}$ Code= while(1){} executed in Flash Peripherals = All ON System Clock = 50 MHz (with PLL)	3	pending ^a	108	pending ^a	mA
	Run mode 2 (Flash loop)	$V_{DD25} = 2.50\text{ V}$ Code= while(1){} executed in Flash Peripherals = All OFF System Clock = 50 MHz (with PLL)	0	pending ^a	53	pending ^a	mA
	Run mode 1 (SRAM loop)	$V_{DD25} = 2.50\text{ V}$ Code= while(1){} executed in SRAM Peripherals = All ON System Clock = 50 MHz (with PLL)	3	pending ^a	102	pending ^a	mA
	Run mode 2 (SRAM loop)	$V_{DD25} = 2.50\text{ V}$ Code= while(1){} executed in SRAM Peripherals = All OFF System Clock = 50 MHz (with PLL)	0	pending ^a	47	pending ^a	mA
I_{DD_SLEEP}	Sleep mode	$V_{DD25} = 2.50\text{ V}$ Peripherals = All OFF System Clock = 50 MHz (with PLL)	0	pending ^a	17	pending ^a	mA
$I_{DD_DEEPSLEEP}$	Deep-Sleep mode	LDO = 2.25 V Peripherals = All OFF System Clock = IOS30KHZ/64	0.143	pending ^a	0.18	pending ^a	mA

a. Pending characterization completion.

22.1.5 Flash Memory Characteristics

Table 22-5. Flash Memory Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
PE_{CYC}	Number of guaranteed program/erase cycles before failure ^a	10,000	100,000	-	cycles
T_{RET}	Data retention at average operating temperature of 85°C	10	-	-	years
T_{PROG}	Word program time	20	-	-	µs
T_{ERASE}	Page erase time	20	-	-	ms
T_{ME}	Mass erase time	200	-	-	ms

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

22.2 AC Characteristics

22.2.1 Load Conditions

Unless otherwise specified, the following conditions are true for all timing measurements. Timing measurements are for 4-mA drive strength.

Figure 22-1. Load Conditions

22.2.2 Clocks

Table 22-6. Phase Locked Loop (PLL) Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
f _{ref_crystal}	Crystal reference ^a	3.579545	-	16.384	MHz
f _{ref_ext}	External clock reference ^a	3.579545	-	16.384	MHz
f _{pll}	PLL frequency ^b	-	400	-	MHz
T _{READY}	PLL lock time	-	-	0.5	ms

a. The exact value is determined by the crystal value programmed into the XTAL field of the **Run-Mode Clock Configuration (RCC)** register.

b. PLL frequency is automatically calculated by the hardware based on the XTAL field of the **RCC** register.

Table 22-7. Clock Characteristics

Parameter	Parameter Name	Min	Nom	Max	Unit
f _{IOSC}	Internal 12 MHz oscillator frequency	8.4	12	15.6	MHz
f _{IOSC30KHZ}	Internal 30 KHz oscillator frequency	21	30	39	KHz
f _{MOSC}	Main oscillator frequency	1	-	16.384	MHz
t _{MOSC_per}	Main oscillator period	61	-	1000	ns
f _{ref_crystal_bypass}	Crystal reference using the main oscillator (PLL in BYPASS mode) ^a	1	-	16.384	MHz
f _{ref_ext_bypass}	External clock reference (PLL in BYPASS mode) ^a	0	-	50	MHz
f _{system_clock}	System clock	0	-	50	MHz

a. The ADC must be clocked from the PLL or directly from a 14-MHz to 18-MHz clock source to operate properly.

Table 22-8. Crystal Characteristics

Parameter Name	Value						Units
Frequency	16	12	8	6	4	3.5	MHz
Frequency tolerance	±50	±50	±50	±50	±50	±50	ppm
Aging	±5	±5	±5	±5	±5	±5	ppm/yr
Oscillation mode	Parallel	Parallel	Parallel	Parallel	Parallel	Parallel	-

Parameter Name	Value						Units
Temperature stability (-40°C to 85°C)	±25	±25	±25	±25	±25	±25	ppm
Motional capacitance (typ)	13.9	18.5	27.8	37.0	55.6	63.5	pF
Motional inductance (typ)	7.15	9.5	14.3	19.1	28.6	32.7	mH
Equivalent series resistance (max)	80	100	120	160	200	220	Ω
Shunt capacitance (max)	10	10	10	10	10	10	pF
Load capacitance (typ)	16	16	16	16	16	16	pF

22.2.5 I²C

Table 22-12. I²C Characteristics

Parameter No.	Parameter	Parameter Name	Min	Nom	Max	Unit
I1 ^a	t _{SCH}	Start condition hold time	36	-	-	system clocks
I2 ^a	t _{LP}	Clock Low period	36	-	-	system clocks
I3 ^b	t _{SRT}	I ² C _{SCL} /I ² C _{SDA} rise time (V _{IL} =0.5 V to V _{IH} =2.4 V)	-	-	(see note b)	ns
I4 ^a	t _{DH}	Data hold time	2	-	-	system clocks
I5 ^c	t _{SFT}	I ² C _{SCL} /I ² C _{SDA} fall time (V _{IH} =2.4 V to V _{IL} =0.5 V)	-	9	10	ns
I6 ^a	t _{HT}	Clock High time	24	-	-	system clocks
I7 ^a	t _{DS}	Data setup time	18	-	-	system clocks
I8 ^a	t _{SCSR}	Start condition setup time (for repeated start condition only)	36	-	-	system clocks
I9 ^a	t _{SCS}	Stop condition setup time	24	-	-	system clocks

- a. Values depend on the value programmed into the TPR bit in the I²C Master Timer Period (I2CMTPR) register; a TPR programmed for the maximum I²C_{SCL} frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I²C interface is designed to scale the actual data transition time to move it to the middle of the I²C_{SCL} Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.
- b. Because I²C_{SCL} and I²C_{SDA} are open-drain-type outputs, which the controller can only actively drive Low, the time I²C_{SCL} or I²C_{SDA} takes to reach a high level depends on external signal capacitance and pull-up resistor values.
- c. Specified at a nominal 50 pF load.

A Boot Loader

A.1 Boot Loader

The Stellaris[®] boot loader is executed from the ROM when flash is empty and is used to download code to the flash memory of a device without the use of a debug interface. The boot loader uses a simple packet interface to provide synchronous communication with the device. The boot loader runs off the internal oscillator and does not enable the PLL, so its speed is determined by the speed of the internal oscillator. The UART0, SSI0 and I²C0 serial interfaces can be used. For simplicity, both the data format and communication protocol are identical for all serial interfaces.

A.2 Interfaces

Once communication with the boot loader is established via one of the serial interfaces, that interface is used until the boot loader is reset or new code takes over. For example, once you start communicating using the SSI port, communications with the boot loader via the UART are disabled until the device is reset.

A.2.1 UART

The Universal Asynchronous Receivers/Transmitters (UART) communication uses a fixed serial format of 8 bits of data, no parity, and 1 stop bit. The baud rate used for communication is automatically detected by the boot loader and can be any valid baud rate supported by the host and the device. The auto detection sequence requires that the baud rate should be no more than 1/32 the internal oscillator frequency of the board that is running the boot loader (which is at least 8.4 MHz, providing support for up to 262,500 baud). This is actually the same as the hardware limitation for the maximum baud rate for any UART on a Stellaris[®] device which is calculated as follows:

$$\text{Max Baud Rate} = \text{System Clock Frequency} / 16$$

In order to determine the baud rate, the boot loader needs to determine the relationship between the internal oscillator and the baud rate. This is enough information for the boot loader to configure its UART to the same baud rate as the host. This automatic baud-rate detection allows the host to use any valid baud rate that it wants to communicate with the device.

The method used to perform this automatic synchronization relies on the host sending the boot loader two bytes that are both 0x55. This generates a series of pulses to the boot loader that it can use to calculate the ratios needed to program the UART to match the host's baud rate. After the host sends the pattern, it attempts to read back one byte of data from the UART. The boot loader returns the value of 0xCC to indicate successful detection of the baud rate. If this byte is not received after at least twice the time required to transfer the two bytes, the host can resend another pattern of 0x55, 0x55, and wait for the 0xCC byte again until the boot loader acknowledges that it has received a synchronization pattern correctly. For example, the time to wait for data back from the boot loader should be calculated as at least $2 * (20(\text{bits/sync}) / \text{baud rate} (\text{bits/sec}))$. For a baud rate of 115200, this time is $2 * (20 / 115200)$ or 0.35 ms.

A.2.2 SSI

The Synchronous Serial Interface (SSI) port also uses a fixed serial format for communications, with the framing defined as Motorola format with SPH set to 1 and SPO set to 1. See "Frame Formats" on page 396 in the SSI chapter for more information on formats for this transfer protocol. Like the UART, this interface has hardware requirements that limit the maximum speed that the SSI clock can run. This allows the SSI clock to be at most 1/12 the the internal oscillator frequency of

the board running the boot loader (which is at least 8.4 MHz, providing support for up to 700 KHz).. Since the host device is the master, the SSI on the boot loader device does not need to determine the clock as it is provided directly by the host.

A.2.3 I²C

The Inter-Integrated Circuit (I²C) port operates in slave mode with a slave address of 0x42. The I²C port will work at both 100 KHz and 400 KHz I²C clock frequency. Since the host device is the master, the I²C on the boot loader device does not need to determine the clock as it is provided directly by the host.

A.3 Packet Handling

All communications, with the exception of the UART auto-baud, are done via defined packets that are acknowledged (ACK) or not acknowledged (NAK) by the devices. The packets use the same format for receiving and sending packets, including the method used to acknowledge successful or unsuccessful reception of a packet.

A.3.1 Packet Format

All packets sent and received from the device use the following byte-packed format.

```
struct
{
  unsigned char ucSize;
  unsigned char ucChecksum;
  unsigned char Data[];
};
```

ucSize	The first byte received holds the total size of the transfer including the size and checksum bytes.
ucChecksum	This holds a simple checksum of the bytes in the data buffer only. The algorithm is Data[0]+Data[1]+...+ Data[ucSize-3].
Data	This is the raw data intended for the device, which is formatted in some form of command interface. There should be ucSize-2 bytes of data provided in this buffer to or from the device.

A.3.2 Sending Packets

The actual bytes of the packet can be sent individually or all at once; the only limitation is that commands that cause flash memory access should limit the download sizes to prevent losing bytes during flash programming. This limitation is discussed further in the section that describes the boot loader command, COMMAND_SEND_DATA (see "COMMAND_SEND_DATA (0x24)" on page 587).

Once the packet has been formatted correctly by the host, it should be sent out over the UART or SSI interface. Then the host should poll the UART *or* SSI interface for the first non-zero data returned from the device. The first non-zero byte will either be an ACK (0xCC) or a NAK (0x33) byte from the device indicating the packet was received successfully (ACK) or unsuccessfully (NAK). This does not indicate that the actual contents of the command issued in the data portion of the packet were valid, just that the packet was received correctly.

A.3.3 Receiving Packets

The boot loader sends a packet of data in the same format that it receives a packet. The boot loader may transfer leading zero data before the first actual byte of data is sent out. The first non-zero byte is the size of the packet followed by a checksum byte, and finally followed by the data itself. There is no break in the data after the first non-zero byte is sent from the boot loader. Once the device communicating with the boot loader receives all the bytes, it must either ACK or NAK the packet to indicate that the transmission was successful. The appropriate response after sending a NAK to the boot loader is to resend the command that failed and request the data again. If needed, the host may send leading zeros before sending down the ACK/NAK signal to the boot loader, as the boot loader only accepts the first non-zero data as a valid response. This zero padding is needed by the SSI interface in order to receive data to or from the boot loader.

A.4 Commands

The next section defines the list of commands that can be sent to the boot loader. The first byte of the data should always be one of the defined commands, followed by data or parameters as determined by the command that is sent.

A.4.1 COMMAND_PING (0X20)

This command simply accepts the command and sets the global status to success. The format of the packet is as follows:

```
Byte[0] = 0x03;  
Byte[1] = checksum(Byte[2]);  
Byte[2] = COMMAND_PING;
```

The ping command has 3 bytes and the value for `COMMAND_PING` is 0x20 and the checksum of one byte is that same byte, making `Byte[1]` also 0x20. Since the ping command has no real return status, the receipt of an ACK can be interpreted as a successful ping to the boot loader.

A.4.2 COMMAND_GET_STATUS (0x23)

This command returns the status of the last command that was issued. Typically, this command should be sent after every command to ensure that the previous command was successful or to properly respond to a failure. The command requires one byte in the data of the packet and should be followed by reading a packet with one byte of data that contains a status code. The last step is to ACK or NAK the received data so the boot loader knows that the data has been read.

```
Byte[0] = 0x03  
Byte[1] = checksum(Byte[2])  
Byte[2] = COMMAND_GET_STATUS
```

A.4.3 COMMAND_DOWNLOAD (0x21)

This command is sent to the boot loader to indicate where to store data and how many bytes will be sent by the `COMMAND_SEND_DATA` commands that follow. The command consists of two 32-bit values that are both transferred MSB first. The first 32-bit value is the address to start programming data into, while the second is the 32-bit size of the data that will be sent. This command also triggers an erase of the full area to be programmed so this command takes longer than other commands. This results in a longer time to receive the ACK/NAK back from the board. This command should be followed by a `COMMAND_GET_STATUS` to ensure that the Program Address and Program size are valid for the device running the boot loader.

The format of the packet to send this command is as follows:

```

Byte[0] = 11
Byte[1] = checksum(Bytes[2:10])
Byte[2] = COMMAND_DOWNLOAD
Byte[3] = Program Address [31:24]
Byte[4] = Program Address [23:16]
Byte[5] = Program Address [15:8]
Byte[6] = Program Address [7:0]
Byte[7] = Program Size [31:24]
Byte[8] = Program Size [23:16]
Byte[9] = Program Size [15:8]
Byte[10] = Program Size [7:0]

```

A.4.4 COMMAND_SEND_DATA (0x24)

This command should only follow a COMMAND_DOWNLOAD command or another COMMAND_SEND_DATA command if more data is needed. Consecutive send data commands automatically increment address and continue programming from the previous location. For packets which do not contain the final portion of the downloaded data, a multiple of four bytes should always be transferred. The command terminates programming once the number of bytes indicated by the COMMAND_DOWNLOAD command has been received. Each time this function is called it should be followed by a COMMAND_GET_STATUS to ensure that the data was successfully programmed into the flash. If the boot loader sends a NAK to this command, the boot loader does not increment the current address to allow retransmission of the previous data. The following example shows a COMMAND_SEND_DATA packet with 8 bytes of packet data:

```

Byte[0] = 11
Byte[1] = checksum(Bytes[2:10])
Byte[2] = COMMAND_SEND_DATA
Byte[3] = Data[0]
Byte[4] = Data[1]
Byte[5] = Data[2]
Byte[6] = Data[3]
Byte[7] = Data[4]
Byte[8] = Data[5]
Byte[9] = Data[6]
Byte[10] = Data[7]

```

A.4.5 COMMAND_RUN (0x22)

This command is used to tell the boot loader to execute from the address passed as the parameter in this command. This command consists of a single 32-bit value that is interpreted as the address to execute. The 32-bit value is transmitted MSB first and the boot loader responds with an ACK signal back to the host device before actually executing the code at the given address. This allows the host to know that the command was received successfully and the code is now running.

```

Byte[0] = 7
Byte[1] = checksum(Bytes[2:6])
Byte[2] = COMMAND_RUN
Byte[3] = Execute Address[31:24]
Byte[4] = Execute Address[23:16]
Byte[5] = Execute Address[15:8]
Byte[6] = Execute Address[7:0]

```

A.4.6 **COMMAND_RESET (0x25)**

This command is used to tell the boot loader device to reset. Unlike the `COMMAND_RUN` command, this allows the initial stack pointer to be read by the hardware and set up for the new code. It can also be used to reset the boot loader if a critical error occurs and the host device wants to restart communication with the boot loader.

```
Byte[0] = 3  
Byte[1] = checksum(Byte[2])  
Byte[2] = COMMAND_RESET
```

The boot loader responds with an ACK signal back to the host device before actually executing the software reset to the device running the boot loader. This allows the host to know that the command was received successfully and the part will be reset.

B ROM DriverLib Functions

B.1 DriverLib Functions Included in the Integrated ROM

The Peripheral Driver Library (DriverLib) APIs that are available in the integrated ROM of the Stellaris[®] family of devices are listed below. The detailed description of each function is available in the *Stellaris[®] ROM User's Guide*.

```
ROM_ADCHardwareOversampleConfigure
    // Configures the hardware oversampling factor of the ADC.

ROM_ADCIntClear
    // Clears sample sequence interrupt source.

ROM_ADCIntDisable
    // Disables a sample sequence interrupt.

ROM_ADCIntEnable
    // Enables a sample sequence interrupt.

ROM_ADCIntStatus
    // Gets the current interrupt status.

ROM_ADCProcessorTrigger
    // Causes a processor trigger for a sample sequence.

ROM_ADCSequenceConfigure
    // Configures the trigger source and priority of a sample sequence.

ROM_ADCSequenceDataGet
    // Gets the captured data for a sample sequence.

ROM_ADCSequenceDisable
    // Disables a sample sequence.

ROM_ADCSequenceEnable
    // Enables a sample sequence.

ROM_ADCSequenceOverflow
    // Determines if a sample sequence overflow occurred.

ROM_ADCSequenceOverflowClear
    // Clears the overflow condition on a sample sequence.

ROM_ADCSequenceStepConfigure
    // Configure a step of the sample sequencer.

ROM_ADCSequenceUnderflow
    // Determines if a sample sequence underflow occurred.

ROM_ADCSequenceUnderflowClear
    // Clears the underflow condition on a sample sequence.
```

ROM_ComparatorConfigure
// Configures a comparator.

ROM_ComparatorIntClear
// Clears a comparator interrupt.

ROM_ComparatorIntDisable
// Disables the comparator interrupt.

ROM_ComparatorIntEnable
// Enables the comparator interrupt.

ROM_ComparatorIntStatus
// Gets the current interrupt status.

ROM_ComparatorRefSet
// Sets the internal reference voltage.

ROM_ComparatorValueGet
// Gets the current comparator output value.

ROM_FlashErase
// Erases a block of flash.

ROM_FlashIntClear
// Clears flash controller interrupt sources.

ROM_FlashIntDisable
// Disables individual flash controller interrupt sources.

ROM_FlashIntEnable
// Enables individual flash controller interrupt sources.

ROM_FlashIntGetStatus
// Gets the current interrupt status.

ROM_FlashProgram
// Programs flash.

ROM_FlashProtectGet
// Gets the protection setting for a block of flash.

ROM_FlashProtectSave
// Saves the flash protection settings.

ROM_FlashProtectSet
// Sets the protection setting for a block of flash.

ROM_FlashUsecGet
// Gets the number of processor clocks per micro-second.

ROM_FlashUsecSet
// Sets the number of processor clocks per micro-second.

```
ROM_FlashUserGet
    // Gets the User Registers

ROM_FlashUserSave
    // Saves the User Registers

ROM_FlashUserSet
    // Sets the User Registers

ROM_GPIODirModeGet
    // Gets the direction and mode of a pin.

ROM_GPIODirModeSet
    // Sets the direction and mode of the specified pin(s).

ROM_GPIOIntTypeGet
    // Gets the interrupt type for a pin.

ROM_GPIOIntTypeSet
    // Sets the interrupt type for the specified pin(s).

ROM_GPIOPadConfigGet
    // Gets the pad configuration for a pin.

ROM_GPIOPadConfigSet
    // Sets the pad configuration for the specified pin(s).

ROM_GPIOPinIntClear
    // Clears the interrupt for the specified pin(s).

ROM_GPIOPinIntDisable
    // Disables interrupts for the specified pin(s).

ROM_GPIOPinIntEnable
    // Enables interrupts for the specified pin(s).

ROM_GPIOPinIntStatus
    // Gets interrupt status for the specified GPIO port.

ROM_GPIOPinRead
    // Reads the values present of the specified pin(s).

ROM_GPIOPinTypeCAN
    // Configures pin(s) for use as a CAN device.

ROM_GPIOPinTypeComparator
    // Configures pin(s) for use as an analog comparator input.

ROM_GPIOPinTypeGPIOInput
    // Configures pin(s) for use as GPIO inputs.

ROM_GPIOPinTypeGPIOOutput
    // Configures pin(s) for use as GPIO outputs.
```

ROM_GPIOPinTypeGPIOOutputOD
// Configures pin(s) for use as GPIO open drain outputs.

ROM_GPIOPinTypeI2C
// Configures pin(s) for use by the I2C peripheral.

ROM_GPIOPinTypePWM
// Configures pin(s) for use by the PWM peripheral.

ROM_GPIOPinTypeSSI
// Configures pin(s) for use by the SSI peripheral.

ROM_GPIOPinTypeTimer
// Configures pin(s) for use by the Timer peripheral.

ROM_GPIOPinTypeUART
// Configures pin(s) for use by the UART peripheral.

ROM_GPIOPinWrite
// Writes a value to the specified pin(s).

ROM_I2CMasterBusBusy
// Indicates whether or not the I2C bus is busy.

ROM_I2CMasterBusy
// Indicates whether or not the I2C Master is busy.

ROM_I2CMasterControl
// Controls the state of the I2C Master module.

ROM_I2CMasterDataGet
// Receives a byte that has been sent to the I2C Master.

ROM_I2CMasterDataPut
// Transmits a byte from the I2C Master.

ROM_I2CMasterDisable
// Disables the I2C master block.

ROM_I2CMasterEnable
// Enables the I2C Master block.

ROM_I2CMasterErr
// Gets the error status of the I2C Master module.

ROM_I2CMasterInitExpClk
// Initializes the I2C Master block.

ROM_I2CMasterIntClear
// Clears I2C Master interrupt sources.

ROM_I2CMasterIntDisable
// Disables the I2C Master interrupt.

```
ROM_I2CMasterIntEnable
    // Enables the I2C Master interrupt.

ROM_I2CMasterIntStatus
    // Gets the current I2C Master interrupt status.

ROM_I2CMasterSlaveAddrSet
    // Sets the address that the I2C Master will place on the bus.

ROM_I2CSlaveDataGet
    // Receives a byte that has been sent to the I2C Slave.

ROM_I2CSlaveDataPut
    // Transmits a byte from the I2C Slave.

ROM_I2CSlaveDisable
    // Disables the I2C slave block.

ROM_I2CSlaveEnable
    // Enables the I2C Slave block.

ROM_I2CSlaveInit
    // Initializes the I2C Slave block.

ROM_I2CSlaveIntClear
    // Clears I2C Slave interrupt sources.

ROM_I2CSlaveIntDisable
    // Disables the I2C Slave interrupt.

ROM_I2CSlaveIntEnable
    // Enables the I2C Slave interrupt.

ROM_I2CSlaveIntStatus
    // Gets the current I2C Slave interrupt status.

ROM_I2CSlaveStatus
    // Gets the I2C Slave module status.

ROM_IntDisable
    // Disables an interrupt.

ROM_IntEnable
    // Enables an interrupt.

ROM_IntMasterDisable
    // Disables the processor interrupt.

ROM_IntMasterEnable
    // Enables the processor interrupt.

ROM_IntPriorityGet
    // Gets the priority of an interrupt.
```

ROM_IntPriorityGroupingGet
// Gets the priority grouping of the interrupt controller.

ROM_IntPriorityGroupingSet
// Sets the priority grouping of the interrupt controller.

ROM_IntPrioritySet
// Sets the priority of an interrupt.

ROM_PWMDeadBandDisable
// Disables the PWM dead band output.

ROM_PWMDeadBandEnable
// Enables the PWM dead band output, and sets the dead band delays.

ROM_PWMFaultIntClear
// Clears the fault interrupt for a PWM module.

ROM_PWMGenConfigure
// Configures a PWM generator.

ROM_PWMGenDisable
// Disables the timer/counter for a PWM generator block.

ROM_PWMGenEnable
// Enables the timer/counter for a PWM generator block.

ROM_PWMGenIntClear
// Clears the specified interrupt(s) for the specified PWM generator block.

ROM_PWMGenIntStatus
// Gets interrupt status for the specified PWM generator block.

ROM_PWMGenIntTrigDisable
// Disables interrupts for the specified PWM generator block.

ROM_PWMGenIntTrigEnable
// Enables interrupts and triggers for the specified PWM generator block.

ROM_PWMGenPeriodGet
// Gets the period of a PWM generator block.

ROM_PWMGenPeriodSet
// Set the period of a PWM generator.

ROM_PWMIntDisable
// Disables generator and fault interrupts for a PWM module.

ROM_PWMIntEnable
// Enables generator and fault interrupts for a PWM module.

ROM_PWMIntStatus
// Gets the interrupt status for a PWM module.

ROM_PWMOutputFault
// Specifies the state of PWM outputs in response to a fault condition.

ROM_PWMOutputInvert
// Selects the inversion mode for PWM outputs.

ROM_PWMOutputState
// Enables or disables PWM outputs.

ROM_PWMPulseWidthGet
// Gets the pulse width of a PWM output.

ROM_PWMPulseWidthSet
// Sets the pulse width for the specified PWM output.

ROM_PWMSyncTimeBase
// Synchronizes the counters in one or multiple PWM generator blocks.

ROM_PWMSyncUpdate
// Synchronizes all pending updates.

ROM_SSIConfigSetExpClk
// Configures the synchronous serial interface.

ROM_SSIDataGet
// Gets a data element from the SSI receive FIFO.

ROM_SSIDataGetNonBlocking
// Gets a data element from the SSI receive FIFO.

ROM_SSIDataPut
// Puts a data element into the SSI transmit FIFO.

ROM_SSIDataPutNonBlocking
// Puts a data element into the SSI transmit FIFO.

ROM_SSIDisable
// Disables the synchronous serial interface.

ROM_SSIEnable
// Enables the synchronous serial interface.

ROM_SSIIntClear
// Clears SSI interrupt sources.

ROM_SSIIntDisable
// Disables individual SSI interrupt sources.

ROM_SSIIntEnable
// Enables individual SSI interrupt sources.

ROM_SSIIntStatus
// Gets the current interrupt status.

ROM_SysCtlADCSpeedGet
// Gets the sample rate of the ADC.

ROM_SysCtlADCSpeedSet
// Sets the sample rate of the ADC.

ROM_SysCtlClockGet
// Gets the processor clock rate.

ROM_SysCtlClockSet
// Sets the clocking of the device.

ROM_SysCtlDeepSleep
// Puts the processor into deep-sleep mode.

ROM_SysCtlFlashSizeGet
// Gets the size of the flash.

ROM_SysCtlGPIOAHBDisable
// Disables a GPIO peripheral for access from the high speed bus.

ROM_SysCtlGPIOAHBEnable
// Enables a GPIO peripheral for access from the high speed bus.

ROM_SysCtlIntClear
// Clears system control interrupt sources.

ROM_SysCtlIntDisable
// Disables individual system control interrupt sources.

ROM_SysCtlIntEnable
// Enables individual system control interrupt sources.

ROM_SysCtlIntStatus
// Gets the current interrupt status.

ROM_SysCtlLDOGet
// Gets the output voltage of the LDO.

ROM_SysCtlLDOSet
// Sets the output voltage of the LDO.

ROM_SysCtlPeripheralClockGating
// Controls peripheral clock gating in sleep and deep-sleep mode.

ROM_SysCtlPeripheralDeepSleepDisable
// Disables a peripheral in deep-sleep mode.

ROM_SysCtlPeripheralDeepSleepEnable
// Enables a peripheral in deep-sleep mode.

ROM_SysCtlPeripheralDisable
// Disables a peripheral.

ROM_SysCtlPeripheralEnable
// Enables a peripheral.

ROM_SysCtlPeripheralPresent
// Determines if a peripheral is present.

ROM_SysCtlPeripheralReset
// Performs a software reset of a peripheral.

ROM_SysCtlPeripheralSleepDisable
// Disables a peripheral in sleep mode.

ROM_SysCtlPeripheralSleepEnable
// Enables a peripheral in sleep mode.

ROM_SysCtlPinPresent
// Determines if a pin is present.

ROM_SysCtlPWMClockGet
// Gets the current PWM clock configuration.

ROM_SysCtlPWMClockSet
// Sets the PWM clock configuration.

ROM_SysCtlReset
// Resets the device.

ROM_SysCtlResetCauseClear
// Clears reset reasons.

ROM_SysCtlResetCauseGet
// Gets the reason for a reset.

ROM_SysCtlSleep
// Puts the processor into sleep mode.

ROM_SysCtlSRAMSizeGet
// Gets the size of the SRAM.

ROM_SysTickDisable
// Disables the SysTick counter.

ROM_SysTickEnable
// Enables the SysTick counter.

ROM_SysTickIntDisable
// Disables the SysTick interrupt.

ROM_SysTickIntEnable
// Enables the SysTick interrupt.

ROM_SysTickPeriodGet
// Gets the period of the SysTick counter.

ROM_SysTickPeriodSet
// Sets the period of the SysTick counter.

ROM_SysTickValueGet
// Gets the current value of the SysTick counter.

ROM_TimerConfigure
// Configures the timer(s).

ROM_TimerControlEvent
// Controls the event type.

ROM_TimerControlLevel
// Controls the output level.

ROM_TimerControlStall
// Controls the stall handling.

ROM_TimerControlTrigger
// Enables or disables the trigger output.

ROM_TimerDisable
// Disables the timer(s).

ROM_TimerEnable
// Enables the timer(s).

ROM_TimerIntClear
// Clears timer interrupt sources.

ROM_TimerIntDisable
// Disables individual timer interrupt sources.

ROM_TimerIntEnable
// Enables individual timer interrupt sources.

ROM_TimerIntStatus
// Gets the current interrupt status.

ROM_TimerLoadGet
// Gets the timer load value.

ROM_TimerLoadSet
// Sets the timer load value.

ROM_TimerMatchGet
// Gets the timer match value.

ROM_TimerMatchSet
// Sets the timer match value.

ROM_TimerPrescaleGet
// Get the timer prescale value.

```
ROM_TimerPrescaleMatchGet
    // Get the timer prescale match value.

ROM_TimerPrescaleMatchSet
    // Set the timer prescale match value.

ROM_TimerPrescaleSet
    // Set the timer prescale value.

ROM_TimerRTCDisable
    // Disable RTC counting.

ROM_TimerRTCEnable
    // Enable RTC counting.

ROM_TimerValueGet
    // Gets the current timer value.

ROM_UARTBreakCtl
    // Causes a BREAK to be sent.

ROM_UARTCharGet
    // Waits for a character from the specified port.

ROM_UARTCharGetNonBlocking
    // Receives a character from the specified port.

ROM_UARTCharPut
    // Waits to send a character from the specified port.

ROM_UARTCharPutNonBlocking
    // Sends a character to the specified port.

ROM_UARTCharsAvail
    // Determines if there are any characters in the receive FIFO.

ROM_UARTConfigGetExpClk
    // Gets the current configuration of a UART.

ROM_UARTConfigSetExpClk
    // Sets the configuration of a UART.

ROM_UARTDisable
    // Disables transmitting and receiving.

ROM_UARTDisableSIR
    // Disables SIR (IrDA) mode on the specified UART.

ROM_UARTEnable
    // Enables transmitting and receiving.

ROM_UARTEnableSIR
    // Enables SIR (IrDA) mode on specified UART.
```

ROM_UARTFIFOLevelGet
// Gets the FIFO level at which interrupts are generated.

ROM_UARTFIFOLevelSet
// Sets the FIFO level at which interrupts are generated.

ROM_UARTIntClear
// Clears UART interrupt sources.

ROM_UARTIntDisable
// Disables individual UART interrupt sources.

ROM_UARTIntEnable
// Enables individual UART interrupt sources.

ROM_UARTIntStatus
// Gets the current interrupt status.

ROM_UARTParityModeGet
// Gets the type of parity currently being used.

ROM_UARTParityModeSet
// Sets the type of parity.

ROM_UARTSpaceAvail
// Determines if there is any space in the transmit FIFO.

ROM_UpdateI2C
// Starts an update over the I2C0 interface.

ROM_UpdateSSI
// Starts an update over the SSI0 interface.

ROM_UpdateUART
// Starts an update over the UART0 interface.

ROM_WatchdogEnable
// Enables the watchdog timer.

ROM_WatchdogIntClear
// Clears the watchdog timer interrupt.

ROM_WatchdogIntEnable
// Enables the watchdog timer interrupt.

ROM_WatchdogIntStatus
// Gets the current watchdog timer interrupt status.

ROM_WatchdogLock
// Enables the watchdog timer lock mechanism.

ROM_WatchdogLockState
// Gets the state of the watchdog timer lock mechanism.

ROM_WatchdogReloadGet
// Gets the watchdog timer reload value.

ROM_WatchdogReloadSet
// Sets the watchdog timer reload value.

ROM_WatchdogResetDisable
// Disables the watchdog timer reset.

ROM_WatchdogResetEnable
// Enables the watchdog timer reset.

ROM_WatchdogRunning
// Determines if the watchdog timer is enabled.

ROM_WatchdogStallDisable
// Disables stalling of the watchdog timer during debug events.

ROM_WatchdogStallEnable
// Enables stalling of the watchdog timer during debug events.

ROM_WatchdogUnlock
// Disables the watchdog timer lock mechanism.

ROM_WatchdogValueGet
// Gets the current watchdog timer value.

D Ordering and Contact Information

D.1 Ordering Information

Table D-1. Part Ordering Information

Orderable Part Number	Description
LM3S2671-IQR50	Stellaris® LM3S2671 Microcontroller
LM3S2671-IQR50(T)	Stellaris® LM3S2671 Microcontroller

D.2 Kits

The Luminary Micro Stellaris® Family provides the hardware and software tools that engineers need to begin development quickly.

- Reference Design Kits accelerate product development by providing ready-to-run hardware, and comprehensive documentation including hardware design files:
http://www.luminarymicro.com/products/reference_design_kits/
- Evaluation Kits provide a low-cost and effective means of evaluating Stellaris® microcontrollers before purchase:
<http://www.luminarymicro.com/products/kits.html>
- Development Kits provide you with all the tools you need to develop and prototype embedded applications right out of the box:
http://www.luminarymicro.com/products/development_kits.html

See the Luminary Micro website for the latest tools available, or ask your Luminary Micro distributor.

D.3 Company Information

Luminary Micro, Inc. designs, markets, and sells ARM Cortex-M3-based microcontrollers (MCUs). Austin, Texas-based Luminary Micro is the lead partner for the Cortex-M3 processor, delivering the world's first silicon implementation of the Cortex-M3 processor. Luminary Micro's introduction of the

Stellaris® family of products provides 32-bit performance for the same price as current 8- and 16-bit microcontroller designs. With entry-level pricing at \$1.00 for an ARM technology-based MCU, Luminary Micro's Stellaris product line allows for standardization that eliminates future architectural upgrades or software tool changes.

Luminary Micro, Inc.
108 Wild Basin, Suite 350
