### 1.5 V to $\mathbf{3 . 6 \mathrm { V } , 3 1 2 . 5 \mathrm { ksps } ,}$ 1-Channel True-Differential/ 2-Channel Single-Ended, 12-Bit, SAR ADCs

General Description
The MAX1393/MAX1396 micropower, serial-output, 12bit, analog-to-digital converters (ADCs) operate with a single power supply from +1.5 V to +3.6 V . These ADCs feature automatic shutdown, fast wake-up, and a highspeed 3-wire interface. Power consumption is only $0.734 \mathrm{~mW}(\mathrm{VDD}=+1.5 \mathrm{~V})$ at the maximum conversion rate of 312.5 ksps . AutoShutdown ${ }^{\text {TM }}$ between conversions reduces power consumption at slower throughput rates.
The MAX1393/MAX1396 require an external reference $V_{\text {REF }}$ that has a wide range from 0.6 V to $\mathrm{V}_{\mathrm{DD}}$. The MAX1393 provides one true-differential analog input that accepts signals ranging from 0 to VREF (unipolar mode) or $\pm V_{\text {REF }} / 2$ (bipolar mode). The MAX1396 provides two single-ended inputs that accept signals ranging from 0 to VREF. Analog conversion results are available through a 5 MHz 3 -wire SPI ${ }^{\text {TM }}$-/QSPITM-/ MICROWIRE ${ }^{\text {TM }}$-/digital signal processor (DSP)-compatible serial interface. Excellent dynamic performance, low voltage, low power, ease of use, and small package sizes make these converters ideal for portable bat-tery-powered data-acquisition applications, and for other applications that demand low power consumption and minimal space.
The MAX1393/MAX1396 are available in a space-saving (3mm $\times 3 \mathrm{~mm}$ ) 10-pin TDFN package. The parts operate over the extended $\left(-40^{\circ} \mathrm{C}\right.$ to $\left.+85^{\circ} \mathrm{C}\right)$ and military $\left(-55^{\circ} \mathrm{C}\right.$ to $\left.+125^{\circ} \mathrm{C}\right)$ temperature ranges.

## Applications

Portable Datalogging
Data Acquisition
Medical Instruments
Battery-Powered Instruments
Process Control

- 312.5ksps, 12-Bit Successive-Approximation Register (SAR) ADCs
- Single True-Differential Analog Input Channel with Unipolar-/Bipolar-Select Input (MAX1393)
- Dual Single-Ended Input Channel with ChannelSelect Input (MAX1396)
- $\pm 1$ LSB INL, $\pm 1$ LSB DNL, No Missing Codes
- $\pm 2$ LSB Total Unadjusted Error (TUE)
- 70dB SINAD at 75kHz Input Frequency
- External Reference (0.6V to VDD)
- Single-Supply Voltage (+1.5V to +3.6V)
- 0.915 mW at $300 \mathrm{ksps}, 1.8 \mathrm{~V}$
- 0.305 mW at $100 \mathrm{ksps}, 1.8 \mathrm{~V}$
- $3.1 \mu \mathrm{~W}$ at $1 \mathrm{ksps}, 1.8 \mathrm{~V}$
- $<1 \mu \mathrm{~A}$ Shutdown Current
- AutoShutdown Between Conversions
- SPI-/QSPI-/MICROWIRE-/DSP-Compatible, 3- or 4-Wire Serial Interface
- Small (3mm x 3mm) 10-Pin TDFN Package

Typical Operating Circuit and Pin Configurations appear at end of data sheet.

Pin Description

| PIN |  | NAME | FUNCTION |
| :---: | :---: | :---: | :---: |
| MAX1393 | MAX1396 |  |  |
| 1 | 1 | $V_{D D}$ | Positive Supply Voltage. Connect VDD to a 1.5 V to 3.6 V power supply. Bypass $\mathrm{V}_{\mathrm{DD}}$ to GND with a $0.1 \mu \mathrm{~F}$ capacitor as close to the device as possible. |
| 2 | - | AIN- | Negative Analog Input |
| - | 2 | AIN2 | Analog Input Channel 2 |
| 3 | - | $\mathrm{AlN}+$ | Positive Analog Input |
| - | 3 | AIN1 | Analog Input Channel 1 |
| 4 | 4 | GND | Ground |
| 5 | 5 | REF | External Reference Voltage Input. $V_{\text {REF }}=0.6 \mathrm{~V}$ to ( $\mathrm{V}_{\mathrm{DD}}+0.05 \mathrm{~V}$ ). Bypass REF to GND with a $0.1 \mu \mathrm{~F}$ capacitor as close to the device as possible. |
| 6 | - | UNI/ $\overline{\mathrm{BIP}}$ | Input-Mode Select. Drive UNI/ $\overline{\mathrm{BIP}}$ high to select unipolar input mode. Pull UNI// $\overline{\mathrm{BIP}}$ low to select bipolar input mode. In unipolar mode, the output data is in straight binary format. In bipolar mode, the output data is in two's complement format. |
| - | 6 | $\overline{\mathrm{CH} 1 / \mathrm{CH} 2}$ | Channel-Select Input. Pull $\overline{\mathrm{CH} 1} / \mathrm{CH} 2$ low to select channel 1. Drive $\overline{\mathrm{CH} 1} / \mathrm{CH} 2$ high to select channel 2. |
| 7 | 7 | $\overline{\mathrm{OE}}$ | Active-Low Output Enable. Pull $\overline{\mathrm{OE}}$ low to enable DOUT. Drive $\overline{\mathrm{OE}}$ high to disable DOUT. Connect to $\overline{\mathrm{CS}}$ to interface with SPI, QSPI, and MICROWIRE devices or set low to interface with DSP devices. |
| 8 | 8 | $\overline{\mathrm{CS}}$ | Active-Low Chip-Select Input. A falling edge on $\overline{\mathrm{CS}}$ initiates power-up and acquisition. |
| 9 | 9 | DOUT | Serial-Data Output. DOUT changes state on the falling edge of SCLK. DOUT is high impedance when $\overline{\mathrm{OE}}$ is high. |
| 10 | 10 | SCLK | Serial-Clock Input. SCLK drives the conversion process and clocks data out. Acquisition ends on the 3rd falling edge after the $\overline{\mathrm{CS}}$ falling edge. The LSB is clocked out on the SCLK 15th falling edge and the device enters AutoShutdown mode (see Figures 8,9 , and 10). |
| - | - | EP | Exposed Pad. Not internally connected. Connect the exposed pad to GND or leave floating. |

## Detailed Description

The MAX1393/MAX1396 use an input track and hold (T/H) circuit along with a SAR to convert an analog input signal to a serial 12 -bit digital output data stream. The serial interface provides easy interfacing to microprocessors and DSPs. Figure 3 shows the simplified functional diagram for the MAX1393 (1 channel, true differential) and the MAX1396 (2 channels, single ended).

True-Differential Analog Input T/H The equivalent input circuit of Figure 4 shows the MAX1393/MAX1396 input architecture, which is composed of a T/H, a comparator, and a switched-capacitor DAC. The T/H enters its tracking mode on the falling edge of $\overline{C S}$ (while $\overline{O E}$ is held low). The positive input capacitor is connected to AIN+ (MAX1393), or to AIN1 or AIN2 (MAX1396). The negative input capacitor is connected to AIN- (MAX1393) or GND (MAX1396). The T/H enters its hold mode on the 3rd falling edge of SCLK

Figure 3. Simplified Functional Diagram

### 1.5V to 3.6V, 312.5ksps, 1-Channel True-Differential/ 2-Channel Single-Ended, 12-Bit, SAR ADCs

and the difference between the sampled positive and negative input voltages is converted. The time required for the $\mathrm{T} / \mathrm{H}$ to acquire an input signal is determined by how quickly its input capacitance is charged. The required acquisition time lengthens as the input signal's source impedance increases. The acquisition time, tACQ, is the minimum time needed for the signal to be acquired. It is calculated by the following equation:

$$
t_{A C Q} \geq 9 \times(\text { RSOURCE }+ \text { RIN }) \times \text { CIN }+ \text { tpU }
$$

where:
RSOURCE is the source impedance of the input signal.
RIN $=500 \Omega$, which is the equivalent differential analog input resistance.
CIN $=16 \mathrm{pF}$, which is the equivalent differential analog input capacitance.
tPu $=400 \mathrm{~ns}$.
Note: $\mathrm{t}_{\mathrm{ACQ}}$ is never less than 600 ns and any source impedance below $400 \Omega$ does not significantly affect the ADC's AC performance.

Figure 4. Equivalent Input Circuit

## Analog Input Bandwidth

The ADC's input-tracking circuitry has a 4 MHz fullpower bandwidth, making it possible to digitize highspeed transient events and measure periodic signals with bandwidths exceeding the ADC's sampling rate by using undersampling techniques.
Use anti-alias filtering to avoid high-frequency signals being aliased into the frequency band of interest.

Analog Input Range and Protection
The MAX1393/MAX1396 produce a digital output that corresponds to the analog input voltage as long as the analog inputs are within their specified range. When operating the MAX1393 in unipolar mode (UNI/BIP = 1), the specified differential analog input range is from 0 to VREF. When operating in bipolar mode (UNI/BIP $=0$ ), the differential analog input range is from $-V_{R E F} / 2$ to $+V_{R E F} / 2$ with a common-mode range of 0 to VDD. The MAX1396 has an input range from 0 to VREF.
Internal protection diodes confine the analog input voltage within the region of the analog power input rails (VDD, GND) and allow the analog input voltage to swing from GND -0.3 V to $\mathrm{VDD}+0.3 \mathrm{~V}$ without damage. Input voltages beyond GND - 0.3V and VDD + 0.3V forward bias the internal protection diodes. In this situation, limit the forward diode current to less than 50 mA to avoid damage to the MAX1393/MAX1396.

## Output Data Format

Figures 8, 9, and 10 illustrate the conversion timing for the MAX1393/MAX1396. Sixteen SCLK cycles are required to read the conversion result and data on DOUT transitions on the falling edge of SCLK. The conversion result contains 4 zeros, followed by 12 data bits with the data in MSB-first format. For the MAX1393, data is straight binary for unipolar mode and two's complement for bipolar mode. For the MAX1396, data is always straight binary.

Transfer Function
Figure 5 shows the unipolar transfer function for the MAX1393/MAX1396. Figure 6 shows the bipolar transfer function for the MAX1393. Code transitions occur halfway between successive-integer LSB values.

# 1.5V to 3.6V, 312.5ksps, 1-Channel True-Differential/ 2-Channel Single-Ended, 12-Bit, SAR ADCs 

Figure 5. Unipolar Transfer Function

## Applications Information

Starting a Conversion
A falling edge on $\overline{\mathrm{CS}}$ initiates the power-up sequence and begins acquiring the analog input as long as $\overline{\mathrm{OE}}$ is also asserted low. On the 3rd SCLK falling edge, the analog input is held for conversion. The most significant bit (MSB) decision is made and clocked onto DOUT on the 4th SCLK falling edge. Valid DOUT data is available to be clocked into the master (microcontroller ( $\mu \mathrm{C}$ )) on the following SCLK rising edge. The rest of the bits are decided and clocked out to DOUT on each successive SCLK falling edge. See Figures 8 and 9 for conversion timing diagrams.
Once a conversion has been initiated, $\overline{\mathrm{CS}}$ can go high at any time. Further falling edges of $\overline{\mathrm{CS}}$ do not reinitiate an acquisition cycle until the current conversion completes. Once a conversion completes, the first falling edge of $\overline{\mathrm{CS}}$ begins another acquisition/conversion cycle.

Figure 6. Bipolar Transfer Function

## Selecting Unipolar or Bipolar Mode

 (MAX1393 Only)Drive UNI/EIP high to select unipolar mode or pull UNI/BIP low to select bipolar mode. UNI/BIP can be connected to VDD for logic high, to GND for logic low, or actively driven. UNI/历IP needs to be stable for tUBS prior to the first rising edge of SCLK after the $\overline{\mathrm{CS}}$ falling edge (see Figure 1) for a valid conversion result when being actively driven.

## Selecting Analog Input AIN1 or AIN2 (MAX1396 Only)

Pull $\overline{\mathrm{CH} 1} / \mathrm{CH} 2$ low to select AIN1 or drive $\overline{\mathrm{CH}} / \mathrm{CH} 2$ high to select AIN2 for conversion. $\overline{\mathrm{CH} 1} / \mathrm{CH} 2$ can be connected to VDD for logic high, to GND for logic low, or actively driven. $\overline{\mathrm{CH} 1} / \mathrm{CH} 2$ needs to be stable for t CHS prior to the first rising edge of SCLK after the $\overline{\mathrm{CS}}$ falling edge (see Figure 1) for a valid conversion result when being actively driven.

# 1.5V to 3.6V, 312.5ksps, 1-Channel True-Differential/ 2-Channel Single-Ended, 12-Bit, SAR ADCs 

AutoShutdown Mode
The ADC automatically powers down on the SCLK falling edge that clocks out the LSB. This is the falling edge after the 15th SCLK. DOUT goes low when the LSB has been clocked into the master ( $\mu \mathrm{C}$ ) on the 16th rising SCLK edge.
Alternatively, drive $\overline{\mathrm{OE}}$ high to force the MAX1393/ MAX1396 into power-down. Whenever $\overline{\mathrm{OE}}$ goes high, the ADC powers down and disables DOUT regardless of $\overline{C S}$, SCLK, or the state of the ADC. DOUT enters a high-impedance state after tDOD.

External Reference
The MAX1393/MAX1396 use an external reference between 0.6 V and (VDD +50 mV ). Bypass REF with a

$0.1 \mu \mathrm{~F}$ capacitor to GND for best performance (see the Typical Operating Circuit).

Serial Interface
The MAX1393/MAX1396 serial interface is fully compatible with SPI, QSPI, and MICROWIRE (see Figure 7). If a serial interface is available, set the $\mu$ C's serial interface in master mode so the $\mu \mathrm{C}$ generates the serial clock. Choose a clock frequency between 100 kHz and 5 MHz . $\overline{\mathrm{CS}}$ and $\overline{\mathrm{OE}}$ can be connected together and driven simultaneously. $\overline{\mathrm{OE}}$ can also be connected to GND if the DOUT bus is not shared and driven independently.

## SPI and MICROWIRE

When using SPI or MICROWIRE, make the $\mu \mathrm{C}$ the bus master and set $\mathrm{CPOL}=0$ and $\mathrm{CPHA}=0$ or $\mathrm{CPOL}=1$ and CPHA $=1$. (These are the bits in the SPI or MICROWIRE control register.) Two consecutive 1-byte reads are required to get the entire 12-bit result from the ADC. DOUT transitions on SCLK's falling edge and is clocked into the $\mu \mathrm{C}$ on the SCLK's rising edge. See Figure 7 for connections and Figures 8 and 9 for timing diagrams. The conversion result contains 4 zeros, followed by the 12 data bits with the data in MSB-first format. When using CPOL $=0$ and CPHA $=0$ or CPOL $=1$ and CPHA = 1, the MSB of the data is clocked into the $\mu \mathrm{C}$ on the SCLK's fifth rising edge. To be compatible with SPI and MICROWIRE, connect $\overline{\mathrm{CS}}$ and $\overline{\mathrm{OE}}$ together and drive simultaneously.

## QSPI

Unlike SPI, which requires two 1-byte reads to acquire the 12 bits of data from the ADC, QSPI allows the minimum number of clock cycles necessary to clock in the data. However, the MAX1393/MAX1396 require 16 clock cycles from the $\mu \mathrm{C}$ to clock out the 12 bits of data. See Figure 7 for connections and Figures 8 and 9 for timing diagrams. The conversion result contains 4 zeros, followed by the 12 data bits with the data in MSB-first format. When using CPOL $=0$ and CPHA $=0$ or CPOL $=1$ and CPHA $=1$, the MSB of the data is clocked into the $\mu \mathrm{C}$ on the SCLK's fifth rising edge. To be compatible with QSPI, connect $\overline{\mathrm{CS}}$ and $\overline{\mathrm{OE}}$ together and drive simultaneously.

DSP Interface
Figure 10 shows the timing for DSP operation. Figure 11 shows the connections between the MAX1393/ MAX1396 and several common DSPs.

Figure 7. Common Serial-Interface Connections to the MAX1393/MAX1396

Figure 10. DSP Serial-Timing Diagram

As shown in Figure 11, drive the MAX1393/MAX1396 chip-select input ( $\overline{\mathrm{CS}}$ ) with the DSP's frame-sync signal. $\overline{O E}$ may be connected to GND or driven independently. For continuous conversion operation, keep $\overline{\mathrm{OE}}$ low and make the $\overline{\mathrm{CS}}$ falling edge coincident with the 16th falling edge of the SCLK.

## Unregulated Two-Cell or Single Lithium LiMnO2 Cell Operation

Low operating voltage (1.5V to 3.6V) and ultra-low-power consumption make the MAX1393/MAX1396 ideal for low cost, unregulated, battery-powered applications without the need for a DC-DC converter. Power the MAX1393/ MAX1396 directly from two alkaline/NiMH/NiCd cells in series or a single lithium coin cell as shown in the Typical Operating Circuit.
Fresh alkaline cells have a voltage of approximately 1.5 V per cell ( 3 V with 2 cells in series) and approach end of life at 0.8 V ( 1.6 V with 2 cells in series). A typical 2xAA alkaline discharge curve is shown in Figure 12a. A typical CR2032 lithium $\left(\mathrm{LiMnO}_{2}\right)$ coin cell discharge curve is shown in Figure 12b.

Layout, Grounding, and Bypassing
For best performance, use PC boards. Board layout must ensure that digital and analog signal lines are separated from each other. Do not run analog and digital (especially clock) lines parallel to one another, or digital lines underneath the ADC package.

Figure 13 shows the recommended system ground connections. Establish a single-point analog ground (star ground point) at the MAX1393/MAX1396s' GND pin or use the ground plane.
High-frequency noise in the power supply (VDD) degrades the ADC's performance. Bypass VDD to GND with a $0.1 \mu \mathrm{~F}$ capacitor as close to the device as possible. Minimize capacitor lead lengths for best supply noise rejection. To reduce the effects of supply noise, a $10 \Omega$ resistor can be connected as a lowpass filter to attenuate supply noise.

## Exposed Pad

The MAX1393/MAX1396 TDFN package has an exposed pad on the bottom of the package. This pad is not internally connected. Connect the exposed pad to the GND pin on the MAX1393/MAX1396 or leave floating for proper electrical performance.

Definitions
Integral Nonlinearity (INL)
INL is the deviation of the values on an actual transfer function from a straight line. For the MAX1393/ MAX1396, this straight line is between the end points of the transfer function once offset and gain errors have been nullified. INL deviations are measured at every step and the worst-case deviation is reported in the Electrical Characteristics section.

### 1.5V to 3.6V, 312.5ksps, 1-Channel True-Differential/ 2-Channel Single-Ended, 12-Bit, SAR ADCs

Figure 11. Common DSP Connections to the MAX1393/MAX1396
Differential Nonlinearity (DNL)
DNL is the difference between an actual step width and the ideal value of 1 LSB. A DNL error specification of less than $\pm 1$ LSB guarantees no missing codes and a monotonic transfer function. For the MAX1393/ MAX1396, DNL deviations are measured at every step and the worst-case deviation is reported in the Electrical Characteristics section.

Figure 12a. Typical 2xAA Discharge Curve at 100ksps

Figure 12b. Typical CR2032 Discharge Curve at 100ksps
Signal-to-Noise Plus Distortion (SINAD)
SINAD is computed by taking the ratio of the RMS signal to the RMS noise plus the RMS distortion. RMS noise includes all spectral components to the Nyquist frequency excluding the fundamental, the first five harmonics (HD2-HD6), and the DC offset. RMS distortion includes the first five harmonics (HD2-HD6):

SINAD $=20 \times \log \left(\frac{\text { SIGNAL }_{\text {RMS }}}{\sqrt{\text { NOISE }_{\text {RMS }}{ }^{2}+\text { DISTORTION }_{\text {RMS }}{ }^{2}}}\right)$

### 1.5V to 3.6V, 312.5ksps, 1-Channel True-Differential/ 2-Channel Single-Ended, 12-Bit, SAR ADCs

Figure 13. Power-Supply Grounding Connections

## Signal-to-Noise Ratio (SNR)

SNR is a dynamic figure of merit that indicates the converter's noise performance. For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization error only and results directly from the ADC's resolution ( N bits):

$$
\mathrm{SNR} \mathrm{~dB}^{2}[\max ]=6.02 \mathrm{~dB} \times \mathrm{N}+1.76 \mathrm{~dB}
$$

In reality, there are other noise sources such as thermal noise, reference noise, and clock jitter that also degrade SNR. SNR is computed by taking the ratio of the RMS signal to the RMS noise. RMS noise includes all spectral components to the Nyquist frequency excluding the fundamental, the first five harmonics, and the DC offset.

## Total Harmonic Distortion (THD)

THD is a dynamic figure of merit that indicates how much harmonic distortion the converter adds to the signal.
THD is the ratio of the RMS sum of the first five harmonics of the fundamental signal to the fundamental itself. This is expressed as:

where $\mathrm{V}_{1}$ is the fundamental amplitude, and $\mathrm{V}_{2}$ through $V_{6}$ are the amplitudes of the $2 n d$ - through 6th-order harmonics.

## Spurious-Free Dynamic Range (SFDR)

SFDR is a dynamic figure of merit that indicates the lowest usable input signal amplitude. SFDR is the ratio of the RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next-largest spurious component, excluding DC offset. SFDR is specified in decibels relative to the carrier (dBc).

Intermodulation Distortion (IMD)
IMD is the ratio of the RMS sum of the intermodulation products to the RMS sum of the two fundamental input tones. This is expressed as:

$$
I M D=20 \times \log \left(\frac{\sqrt{V_{I M 1}{ }^{2}+V_{I M} 2^{2}+\ldots . .+V_{I M}{ }^{2}+V_{I M N^{2}}}}{\sqrt{V_{1}^{2}+V_{2}^{2}}}\right)
$$

The fundamental input tone amplitudes ( $\mathrm{V}_{1}$ and $\mathrm{V}_{2}$ ) are at -6.5 dBFS . Fourteen intermodulation products ( $\mathrm{V}_{\mathrm{IM}}$ ) are used in the MAX1393/MAX1396 IMD calculation. The intermodulation products are the amplitudes of the output spectrum at the following frequencies, where fin1 and $\mathrm{f} / \mathrm{N} 2$ are the fundamental input tone frequencies:

- 2nd-order intermodulation products: $\mathrm{fin}_{1}+\mathrm{fin}_{\mathrm{I}}, \mathrm{fIN} 2-\mathrm{fIN} 1$
- 3rd-order intermodulation products:

- 4th-order intermodulation products:

- 5th-order intermodulation products: $3 \times \mathrm{fin}_{\mathrm{I}}-2 \times \mathrm{fin}_{\mathrm{IN}}, 3 \times \mathrm{fIN} 2-2 \times \mathrm{fin}_{\mathrm{I}}, 3 \times \mathrm{fin}_{\mathrm{I}}+2 \times$ fin2, $3 \times \mathrm{fin} 2+2 \times \mathrm{fin} 1$

## Channel-to-Channel Crosstalk

Channel-to-channel crosstalk indicates how well each analog input is isolated from the others. The channel-tochannel crosstalk for the MAX1396 is measured by applying DC to channel 2 while an AC sine wave is applied to channel 1. An FFT is taken for channel 1 and channel 2 and the difference (in dB ) is reported as the channel-to-channel crosstalk.

# 1.5V to 3.6V, 312.5ksps, 1-Channel True-Differential/ 2-Channel Single-Ended, 12-Bit, SAR ADCs 

## Aperture Delay

The MAX1393/MAX1396 sample data on the falling edge of its third SCLK cycle (Figure 14). In actuality, there is a small delay between the falling edge of the sampling clock and the actual sampling instant. Aperture delay ( $\mathrm{taD}^{\mathrm{A}}$ ) is the time defined between the falling edge of the sampling clock and the instant when an actual sample is taken.

## Aperture Jitter

Aperture jitter ( $\mathrm{t}_{\mathrm{AJ}}$ ) is the sample-to-sample variation in the aperture delay (Figure 14).

DC Power-Supply Rejection Ratio (PSRR) DC PSRR is defined as the change in the positive fullscale transfer function point caused by a full range variation in the analog power-supply voltage ( $V_{D D}$ ).
