

4MSPS, 24-Bit Analog-to-Digital Converter

FEATURES

- **AC Performance:**
 - 103dB of Dynamic Range at 4MSPS
 - 111dB of Dynamic Range at 125kSPS
 - 107dB THD
- **DC Accuracy:**
 - 3ppm INL
 - 4 μ V/°C Offset Drift
 - 4ppm/°C Gain Drift
- **Programmable Digital Filter with User-Selectable Path:**
 - **Low-Latency: Completely settles in 2.65 μ s**
 - **Wide-Bandwidth: 1.7MHz BW with flat passband**
- **Flexible Read-Only Serial Interface:**
 - **Standard CMOS**
 - **Serialized LVDS**
- **Easy Conversion Control with START Pin**
- **Out-of-Range Detection**
- **Supply: Analog +5V, Digital +3V**
- **Power: 575mW**

APPLICATIONS

- **Automated Test Equipment**
- **Medical Imaging**
- **Scientific Instrumentation**
- **Test and Measurement**

DESCRIPTION

The ADS1675 is a high-speed, high-precision analog-to-digital converter (ADC). Using an advanced delta-sigma ($\Delta\Sigma$) architecture, it operates at speeds up to 4MSPS with outstanding ac performance and dc accuracy.

The ADS1675 ADC is comprised of a low-drift modulator with out-of-range detection and a dual-path programmable digital filter. The dual filter path allows the user to select between two post-processing filters: Low-Latency or Wide-Bandwidth. The Low-Latency filter settles quickly (as fast as 2.65 μ s) for applications with large instantaneous changes, such as a multiplexer. The Wide-Bandwidth path provides an optimized frequency response for ac measurements with a passband ripple of less than ± 0.00002 dB, stop band attenuation of 115dB, and a bandwidth of 1.7MHz.

The device offers two speed modes with distinct interface, resolution, and feature set. In the high-speed mode the device can be set to operate at either 4MSPS or 2MSPS. In the low-speed mode, it can be set to operate at either 1MSPS, 500KSPS, 250KSPS or 125KSPS.

The ADS1675 is controlled through I/O pins—there are no registers to program. A dedicated START pin allows for direct control of conversions: toggle the START pin to begin a conversion, and then retrieve the output data. The flexible serial interface supports data readback with either standard CMOS and LVDS logic levels, allowing the ADS1675 to directly connect to a wide range of microcontrollers, digital signal processors (DSPs), or field-programmable grid arrays (FPGAs).

The ADS1675 operates from an analog supply of 5V and digital supply of 3V, and dissipates 575mW of power. When not in use, the PDWN pin can be used to power down all device circuitry. The device is fully specified over the industrial temperature range and is offered in a TQFP-64 package.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

All trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

PACKAGE/ORDERING INFORMATION

For the most current package and ordering information, see the Package Option Addendum at the end of this data sheet or see the TI web site at www.ti.com.

ABSOLUTE MAXIMUM RATINGS⁽¹⁾

Over operating free-air temperature range, unless otherwise noted.

PARAMETER		ADS1675	UNIT
AVDD to AGND		–0.3 to +5.5	V
DVDD to DGND		–0.3 to +3.6	V
AGND to DGND		–0.3 to +0.3	V
Input current	Momentary	100	mA
	Continuous	10	mA
Analog I/O to AGND		–0.3 to AVDD +0.3	V
Digital I/O to DGND		–0.3 to DVDD +0.3	V
Maximum junction temperature		+150	°C
Operating temperature range		–40 to +85	°C
Storage temperature range		–60 to +150	°C

- (1) Stresses above these ratings may cause permanent damage. Exposure to absolute maximum conditions for extended periods may degrade device reliability. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those specified is not implied.

ELECTRICAL CHARACTERISTICS

All specifications are at $T_A = -40^\circ\text{C}$ to $+85^\circ\text{C}$, $AV_{DD} = 5\text{V}$, $DV_{DD} = 3\text{V}$, $f_{CLK} = 32\text{MHz}$, $V_{REF} = +3\text{V}$, and $R_{BIAS} = 7.5\text{k}\Omega$, unless otherwise noted.

PARAMETER	TEST CONDITIONS	ADS1675			UNIT

PIN		FUNCTION	DESCRIPTION
NAME	NO.		
AVDD	1, 7, 11, 12, 53, 58	Analog	Analog supply
AGND	2, 3, 6, 9, 10, 54, 56, 57	Analog	Analog ground
AINN	4	Analog input	Negative analog input
AINP	5	Analog input	Positive analog input
RBIAS	8	Analog	Analog bias setting resistor
VCM	13	Analog	Terminal for external bypass capacitor connection to internal common-mode voltage
DGND	14-20, 25, 26, 31, 47, 50, 51	Digital	Digital ground
RSV2	21	Reserved	Short pin to digital ground
RSV1	22	Reserved	Short pin to digital supply
DVDD	23, 24, 27, 34, 48, 49, 52	Digital	Digital supply
$\overline{\text{PDWN}}$	28	Digital input	Power-down control, active low
SCLK_SEL	29	Digital input	Shift-clock source select. ⁽¹⁾ If SCLK_SEL = '0', then SCLK is internally generated. If SCLK_SEL = '1', then SCLK must be externally generated.

(1) Option not available in high-speed mode.

Table 1. TERMINAL FUNCTIONS (continued)

PIN		FUNCTION	DESCRIPTION
NAME	NO.		
$\overline{\text{LVDS}}$	30	Digital input	Serial interface select. ⁽¹⁾ If $\overline{\text{LVDS}} = '0'$, then interface is LVDS-compatible. If $\overline{\text{LVDS}} = '1'$, then interface is CMOS-compatible.
LL_CONFIG	32	Digital input	Configure Low-Latency digital filter. ⁽¹⁾ If LL_CONFIG = '0', then single-cycle settling is selected. If LL_CONFIG = '1', then fast-response is selected.
FPATH	33	Digital input	Digital filter path selection. If FPATH = '0', then path is Wide-Bandwidth. If FPATH = '1', then path is Low-Latency.
DRATE[2:0]	34-36	Digital input	Data rate selection
START	37	Digital input	Start convert, reset, and synchronization control input
$\overline{\text{CS}}$	38	Digital input	Chip select; active low
OTRD	39	Digital output	Digital filter out-of-range indicator
OTRA	40	Digital input	Analog input out-of-range indicator
$\overline{\text{SCLK}}$	41	Digital output	Negative shift clock output. If SCLK_SEL = '0', then $\overline{\text{SCLK}}$ is the complementary shift clock output. If SCLK_SEL = '1', then $\overline{\text{SCLK}}$ always output is 3-state.
SCLK	42	Digital input/output	Positive shift clock output. If SCLK_SEL = '0', then SCLK is an output. If SCLK_SEL = '1', then SCLK is an input.
$\overline{\text{DOUT}}$	43	Digital output	Negative LVDS serial data output
DOUT	44	Digital output	Positive LVDS serial data output
$\overline{\text{DRDY}}$	45	Digital output	Negative data ready output
DRDY	46	Digital output	Positive data ready output
CLK	55	Digital input	Master clock input
CAP1	59	Analog	Terminal for 1 μ F external bypass capacitor
VREFN	60, 61	Analog	Negative reference voltage. Short to analog ground
CAP2	62	Analog	Terminal for 1 μ F external bypass capacitor
VREFP	63, 64	Analog	Positive reference voltage

TIMING CHARACTERISTICS

(1) High-speed LVDS valid only for DRATE = 100 and DRATE = 101.

OVERVIEW

The ADS1675 is a 24-bit, delta-sigma ($\Delta\Sigma$) analog-to-digital converter (ADC). It provides high-resolution measurements of both ac and dc signals and features an advanced, multi-stage analog modulator with a programmable and flexible digital decimation filter.

Figure 35 shows a block diagram of the ADS1675. The modulator measures the differential input signal $V_{IN} = (AINP - AINN)$ against the differential reference $V_{REF} = (VREFP - VREFN)$. The digital filter receives the modulator signal and processes it through the user-selected path. The Low-Latency path settles quickly, and is ideal when using a multiplexer or when measuring large transients. The Wide-Bandwidth path provides outstanding frequency response with very low passband ripple, a steep transition band, and large stop band attenuation. This path is well-suited for applications that require high-resolution measurements of high-frequency ac signal content.

A dedicated START pin allows precise conversion control; toggle the pin to begin the conversion process. The ADS1675 is configured by setting the appropriate I/O pins—there are no registers to program. Data are retrieved over a serial interface that can support either CMOS or LVDS voltage levels. In addition, the standard CMOS serial interface can be internally or externally clocked. This flexibility allows direct connection to a wide range of digital hosts including DSPs, FPGAs, and microcontrollers. All data rates are available only using the LVDS mode interface.

A detection circuit monitors the conversions to indicate when the inputs are out-of-range for an extended duration. A power-down pin (PDWN) shuts off all circuitry when the ADS1675 is not in use.

The device offers two speed modes with distinct interfaces, resolution, and feature set. The high-speed mode is enabled by setting DRATE[2:0] to either 100 or 101. The rest of the DRATE configurations enable the low-speed mode.

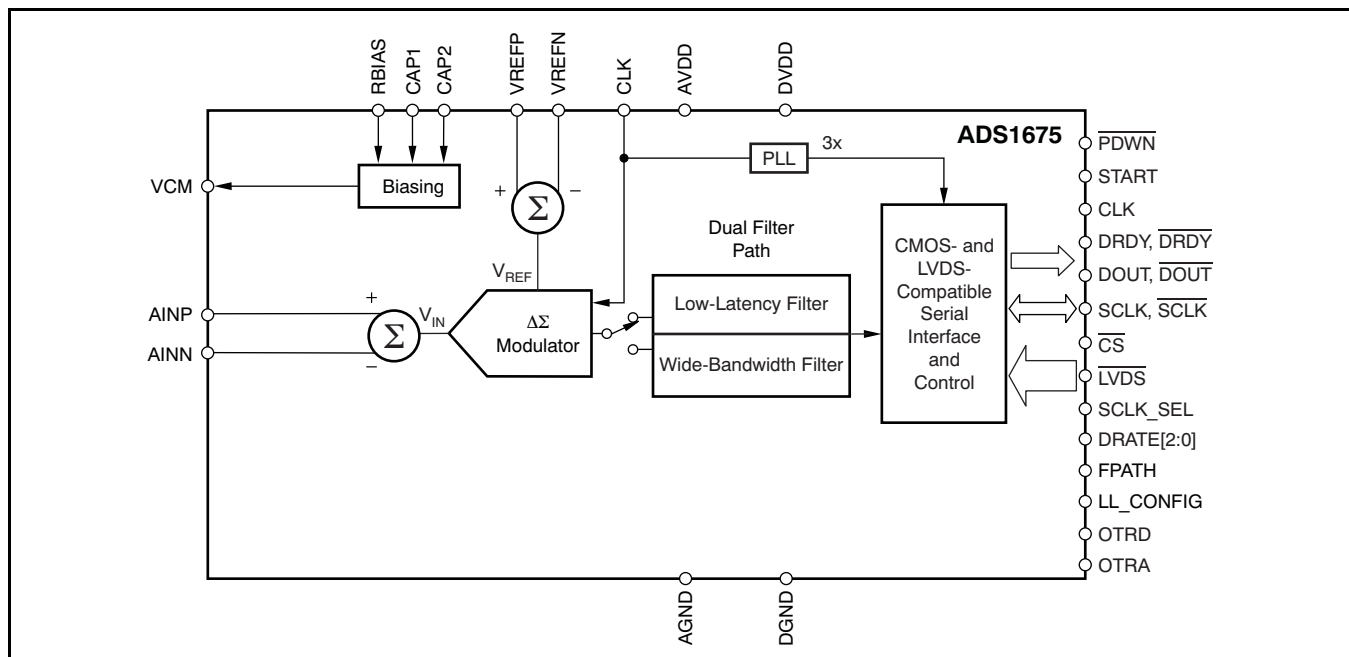

Figure 35. Block Diagram

NOISE PERFORMANCE

The ADS1675 offers outstanding noise performance that can be optimized by adjusting the data rate. As the averaging is increased (thus reducing the data rate), the noise drops correspondingly. Table 2 shows the noise as a function of data rate for both the Low-Latency and the Wide-Bandwidth filter paths under the conditions shown.

Table 2 lists some of the more common methods of specifying noise. The dynamic range is the ratio of the root-mean-square (RMS) value of a full-scale sine wave to the RMS noise with the inputs shorted together. This value is expressed in decibels relative to full-scale (dBFS). The input-referred noise is the RMS value of the noise with the inputs shorted, referred to the input of the ADS1675. The effective number of bits (ENOB) is calculated from a dc perspective using the formula in Equation 1, where full-scale range equals $2V_{REF}$.

$$ENOB = \frac{\ln \left[\frac{\text{Full-scale range}}{\text{RMS noise}} \right]}{\ln(2)} \quad (1)$$

Noise-free bits specifies noise, again from a dc perspective using Equation 1, with peak-to-peak noise substituted for RMS noise.

ANALOG INPUTS (AINP, AINN)

The ADS1675 measures the differential signal, $V_{IN} = (AINP - AINN)$, against the differential reference, $V_{REF} = (VREFP - VREFN)$. The most positive measurable differential input is V_{REF} , which produces the most positive digital output code of 7FFFFFFh. Likewise, the most negative measurable differential input is $-V_{REF}$, which produces the most negative digital output code of 800000h.

Analog inputs must be driven with a differential signal to achieve optimum performance. The recommended common-mode voltage is 2.5V. The ADS1675 samples the analog inputs at very high speeds. It is critical that a suitable driver be used. See the Application Information section for recommended circuit designs.

Table 2. Noise Performance⁽¹⁾

FILTER PATH		DATA RATE[2:0]	DATA RATE (kSPS)	DYNAMIC RANGE (dB)	INPUT-REFERRED NOISE (μV_{RMS})	ENOB	NOISE-FREE BITS
Low-Latency (Fast Response Mode configuration)	Low-speed modes	000	125	111	6.30	19.86	17.14
		001	250	109	7.47	19.61	16.89
		010	500	107	9.51	19.27	16.54
		011	1000	105	11.72	18.97	16.24
	High-speed modes	100	2000	104	13.72	18.74	16.02
		101	4000	103	14.23	18.69	15.96
Wide-Bandwidth	Low-speed modes	000	125	111	6.17	19.89	17.17
		001	250	109	7.44	19.62	16.90
		010	500	107	9.66	19.25	16.52
		011	1000	104	12.99	18.82	16.09
	High-speed modes	100	2000	101	18.64	18.30	15.57
		101	4000	94	44.02	17.06	14.33

(1) $V_{REF} = 3V$, $f_{CLK} = 32MHz$.

VOLTAGE REFERENCE INPUTS (VREFN, VREFP)

The voltage reference for the ADS1675 is the differential voltage between VREFP and VREFN:

$$V_{REF} = (V_{REFP} - V_{REFN})$$

A high-quality reference voltage with the appropriate drive strength is essential for achieving the best performance from the ADS1675. Noise and drift on the reference degrade overall system performance. See the [Application Information](#) section for reference circuit examples.

It is recommended that a minimum 10 μ F and 0.1 μ F ceramic bypass capacitors be used directly across the reference inputs, VREFP and VREFN. These capacitors should be placed as close as possible to the device under test for optimal performance.

COMMON-MODE VOLTAGE (VCM)

The VCM pin outputs a voltage of AVDD/2. The pin must be bypassed with a 1 μ F capacitor placed close to the package pin, even if it is not connected elsewhere. The VCM pin has limited drive ability and therefore must be buffered if connected to a load.

CONVERSION START

The START pin provides an easy and precise conversion control. To perform a single conversion, pulse the START pin as shown in [Figure 36](#). The START signal is latched internally on the rising edge of CLK. Multiple conversions are performed by continuing to hold START high after the first conversion completes; see the digital filter descriptions for more details on multiple conversions, because the timing depends on the filter path selected.

A conversion can be interrupted by issuing another START pulse before the ongoing conversion completes. When an interruption occurs, the data for the ongoing conversion are flushed and a new conversion begins. DRDY indicates that data are ready for retrieval after the filter has settled, as shown in [Figure 37](#).

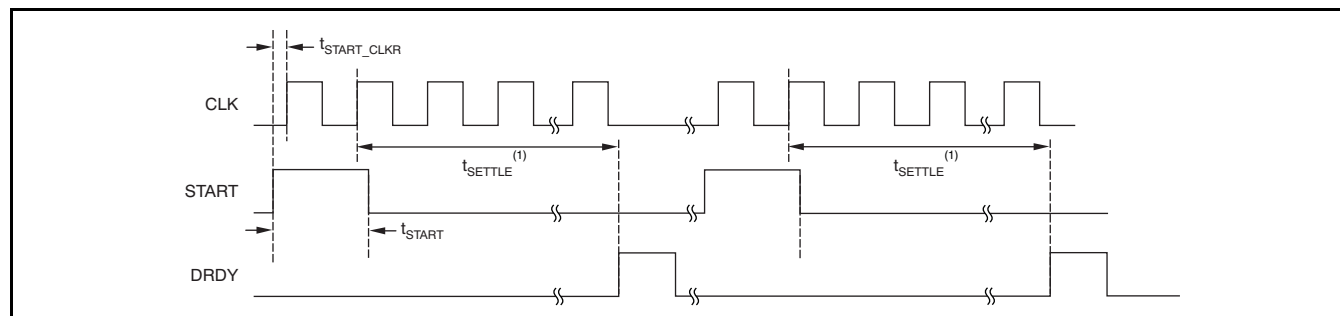

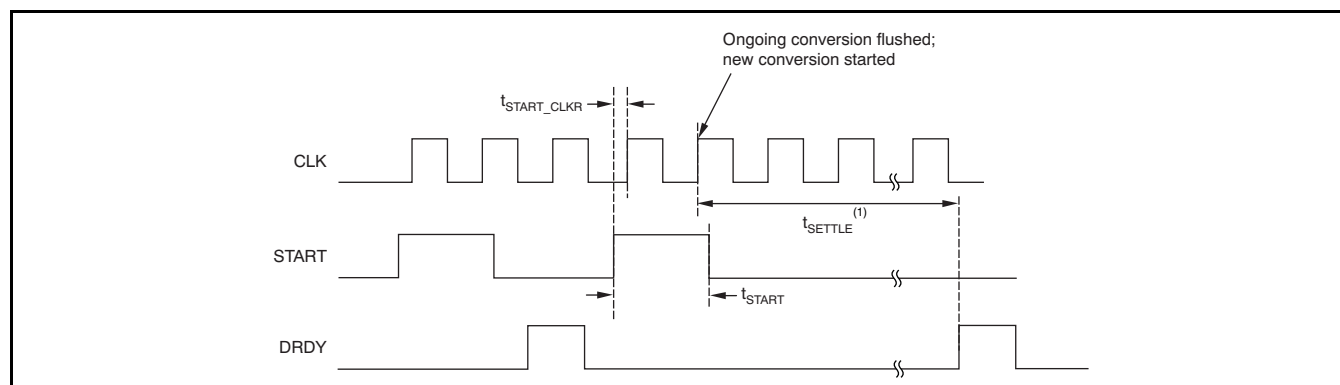

Figure 36. START Pin Used for Single Conversions

(1) See the [Low-Latency Filter](#) and [Wide-Bandwidth Filter](#) sections for specific values of settling time t_{SETTLE} .

Figure 37. Example of Restarting a Conversion with START

DIGITAL FILTER

In $\Delta\Sigma$ ADCs, the digital filter has a critical influence on device performance. The digital filter sets the frequency response, data rate, bandwidth, and settling time. Choosing to optimize some of these features in a filter means that compromises must be made with other specifications. These tradeoffs determine the applications for which the device is best suited.

The ADS1675 offers two digital filters on-chip, and allows the user to direct the output data from the modulator to either the Wide-Bandwidth or Low-Latency filter. These filters allow the user to use one converter design to address multiple applications. The Low-Latency path filter has minimal latency or settling time. This reduction is achieved by reducing the bandwidth of the filter. This path is ideal for measurements with large, quick changes on the inputs (for example, when using a multiplexer). The Low-Latency characteristic allows the user to cycle through the multiplexer at high speeds.

The other path provides a filter with excellent frequency response characteristics. The passband ripple is extremely small, the transition band is very steep, and there is large stop band attenuation. These characteristics are needed for high-resolution measurements of ac signals. The tradeoff here is that settling time increases; for signal processing, however, this increase is not generally a critical concern.

The FPATH digital input pin sets the filter path selection, as shown in Table 3. Note that the START pin must be strobed after a change to the filter path selection or data rate. If a conversion is in process during a filter path or data rate change, the output data are not valid and should be discarded.

Table 3. ADS1675 Filter Path Selection

FPATH PIN	SELECTED FILTER PATH
1	Low-Latency path
0	Wide-Bandwidth path

Table 5. Low-Latency Data Rates with Single-Cycle Settling Configuration

DRATE[2:0]	DATA RATE (kSPS)	SETTLING TIME, $t_{SETTLE-LL}$		-3dB BANDWIDTH (kHz) ⁽¹⁾
000	57.80	17.375 μ s	556 t_{CLK}	54
001	107.53	9.375 μ s	300 t_{CLK}	109
010	188.68	5.375 μ s	172 t_{CLK}	208
011	277.78	3.625 μ s	116 t_{CLK}	344

(1) The input signal aliases when its frequency exceeds $f_{DATA}/2$, in accordance with the Nyquist theorem.

LOW-LATENCY DIGITAL FILTER

The Low-Latency (LL) filter provides a fast settling response targeted for applications that need high-precision measurements with minimal latency. A good example of this type of application is a multiplexer that measures multiple inputs. The faster the ADC settles, the faster the measurement can complete and the multiplexer can advance to the next input.

The ADS1675 LL filter supports two configurations to help optimize performance for these types of applications.

The LL_CONFIG input pin selects the configuration, as shown in Table 4. Be sure to strobe the START pin after changing the configuration. If a conversion is in process during a configuration change, the output data for that conversion are not valid and should be discarded.

Table 4. Low-Latency Pin Configurations

LL_CONFIG PIN	LOW-LATENCY CONFIGURATION
0	Single-cycle settling
1	Fast response

The first configuration is *single-cycle settling*. As the name implies, this configuration allows for the filter to completely settle in one conversion cycle; there is no need to discard data. Each data output is comprised of information taken during only the previous conversion. The DRATE[2:0] digital input pins select the data rate for the Single-Cycle Settling configuration, as shown in Table 5. Note that the START pin must be strobed after a change to the data rate. If a conversion is in process during a data rate change, the output data for that conversion are not valid and should be discarded.

The second configuration is *fast response*. The DRATE[2:0] digital input pins select the data rate for the Fast Response Configuration, as shown in Table 6. When selected, this configuration provides a higher output data rate. The faster output data rate allows for more averaging by a post-processor within a given time interval to reduce noise. It also provides a faster indication of changes on the inputs when monitoring quickly-changing signals (for example, in a control loop application).

Table 6. Low-Latency Data Rates with Fast-Response Configuration

DRATE [2:0]	DATA RATE (kSPS)	SETTLING TIME, $t_{\text{SETTLE-LL}}$		-3dB BANDWIDTH (kHz) ⁽¹⁾
000	125	17.375 μs	556 t_{CLK}	54
001	250	9.375 μs	300 t_{CLK}	109
010	500	5.375 μs	172 t_{CLK}	208
011	1000	3.625 μs	116 t_{CLK}	344
100	2000	2.76 μs ⁽²⁾	265 t_{LSCLK}	350
101	4000	2.385 μs ⁽²⁾	229 t_{LSCLK}	355

(1) The input signal aliases when its frequency exceeds $f_{\text{DATA}}/2$, in accordance with the Nyquist theorem.

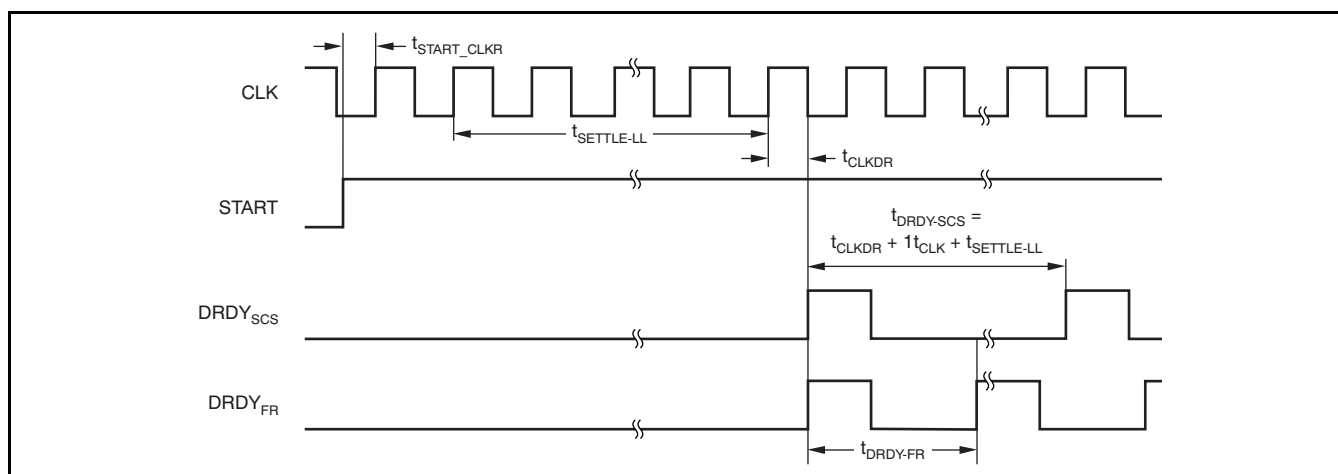

(2) For high-speed mode, the first data are unsettled.

Settling Time

The settling time in absolute time (μs) is the same for both configurations of the Low-Latency filter, as shown in Table 5 and Table 6. The difference between the configurations is seen with the timing of the conversions after the filter has settled from a pulse on the START pin.

Figure 38 illustrates the response of both configurations on approximately the same time scale in order to highlight the differences. With the single-cycle settling configuration, each conversion fully settles; in other words, the conversion period $t_{\text{DRDY-SCS}} = t_{\text{SETTLE-LL}}$. The benefit of this configuration is its simplicity—the ADS1675 functions similar to a successive-approximation register (SAR) converter and there is no need to consider discarding partially-settled data because each conversion is fully settled.

With the fast response configuration, the data rate for conversions after initial settling is faster; that is, the conversion time is less than the settling: $t_{\text{DRDY-FR}} < t_{\text{SETTLE-LL}}$. One benefit of this configuration is a faster response to changes on the inputs, because data are supplied at a faster rate. Another advantage is better support for post-processing. For example, if multiple readings are averaged to reduce noise, the higher data rate of the fast response configuration allows this averaging to happen in less time than it requires with the single-cycle settling filter. A third benefit is the ability to measure higher input frequencies without aliasing as a result of the higher data rate.

NOTE: DRDY_{SCS} is the DRDY output with the Low-Latency single-cycle settling configuration. DRDY_{FR} is the DRDY output with the Low-Latency fast-response settling configuration.

Figure 38. Low-Latency Single-Cycle Settling and Fast-Response Configuration Conversion Timing

It is important to note, however, that the absolute settling time of the Low-Latency path does not change when using the fast response configuration. Changes on the input signal during conversions after the initial settling require multiple cycles to fully settle. To help illustrate this requirement, consider a change on the inputs as shown in Figure 42, where START is assumed to have been taken high before the input voltage was changed.

The readings after a step change in the input is settled as shown in Figure 39 for all different data rates.

Figure 39. Step Response for Low-Latency Filter with Fast-Response Configuration

Frequency Response

Figure 40 shows the frequency response for the Low-Latency filter path normalized to the output data rate, f_{DATA} . The overall frequency response repeats at the modulator sampling rate, which is the same as the input clock frequency. Figure 41 shows the response with the fastest data rate selected (4 MSPS when $f_{CLK} = 32\text{MHz}$).

Figure 40. Frequency Response of Low-Latency Filter in Fast-Response Configuration

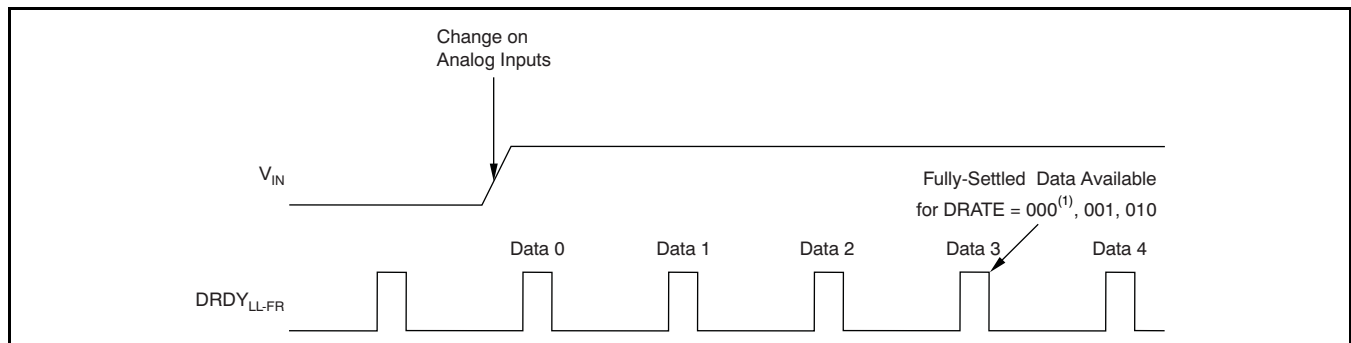

Figure 41. Extended Frequency Response of Low-Latency Path

NOTE: START pin held high previous to change on analog inputs.

(1) Refer to Figure 39 for other modes.

Figure 42. Settling Example with the Low-Latency Filter in Fast-Response Configuration

Phase Response

The Low-Latency filter uses a multiple-stage, linear-phase digital filter. Linear phase filters exhibit constant delay time versus input frequency (also known as *constant group delay*). This feature of linear phase filters means that the time delay from any instant of the input signal to the corresponding same instant of the output data is constant and independent of the input signal frequency. This behavior results in essentially zero phase error when measuring multi-tone signals.

WIDE-BANDWIDTH FILTER

The Wide-Bandwidth (WB) filter is well-suited for measuring high-frequency ac signals. This digital filter offers excellent passband and stop band characteristics.

The DRATE[2:0] digital input pins select from the four data rates available with the WB filter, as shown in Table 7. Note that the START pin must be strobed after a change to the data rate. If a conversion is in process during a data rate change, the output data for that conversion are not valid and should be discarded.

While using the Wide-Bandwidth filter path, the LL_CONFIG pin must be set to logic high. Setting LL_CONFIG low forces the ADS1675 to switch to a low-latency filter path, overriding the FPATH pin.

Table 7. Wide-Bandwidth Data Rates

DRATE [1:0]	DATA RATE (kSPS)	SETTLING TIME, $t_{SETTLE-LL}$		-3dB BANDWIDTH H (kHz) ⁽¹⁾
000	125	439.44 μ s	14062 t_{CLK}	59.375
001	250	219.81 μ s	7074 t_{CLK}	118.75
010	500	110.00 μ s	3520 t_{CLK}	237.5
011	1000	55.04 μ s	1763 t_{CLK}	475
100	2000	27.52 μ s	2642 t_{LSCLK}	950
101	4000	13.79 μ s	1324 t_{LSCLK}	1900

(1) The input signal aliases when its frequency exceeds $f_{DATA}/2$, in accordance with the Nyquist theorem.

Frequency Response

Figure 43 shows the frequency response for the Wide-Bandwidth filter path normalized to the output data rate, f_{DATA} . Figure 44 shows the passband ripple, and the transition from passband to stop band is illustrated in Figure 45. These three plots are valid for all of the data rates available on the ADS1675. Simply substitute the selected data rate to express the x-axis in absolute frequency.

Figure 43. Frequency Response of Wide-Bandwidth Filter

Figure 44. Passband Response for Wide-Bandwidth Filter

Figure 45. Transition Band Response for Wide-Bandwidth Filter

The overall frequency response repeats at the modulator sampling rate, which is the same as the input clock frequency. Figure 46 shows the response with the fastest data rate selected (4 MSPS when $f_{CLK} = 32\text{MHz}$).

Figure 46. Extended Frequency Response of Wide-Bandwidth Path

Phase Response

The Wide-Bandwidth filter uses a multiple-stage, linear-phase digital filter. Linear phase filters exhibit constant delay time versus input frequency (also known as *constant group delay*). This feature means that the time delay from any instant of the input signal to the corresponding same instant of the output data is constant and independent of the input signal frequency. This behavior results in essentially zero phase error when measuring multi-tone signals.

Settling Time

The Wide-Bandwidth filter fully settles before indicating data are ready for retrieval after the START pin is taken high, as shown in Figure 48. For this filter, the settling time is larger than the conversion time: $t_{SETTLE-WB} > t_{DRDY-WB}$. Instantaneous steps on the input require multiple conversions to settle if START is not pulsed. Figure 47 shows the settling response with the x-axis normalized to conversions or data-ready cycles. The output is fully settled after 55 data-ready cycles.

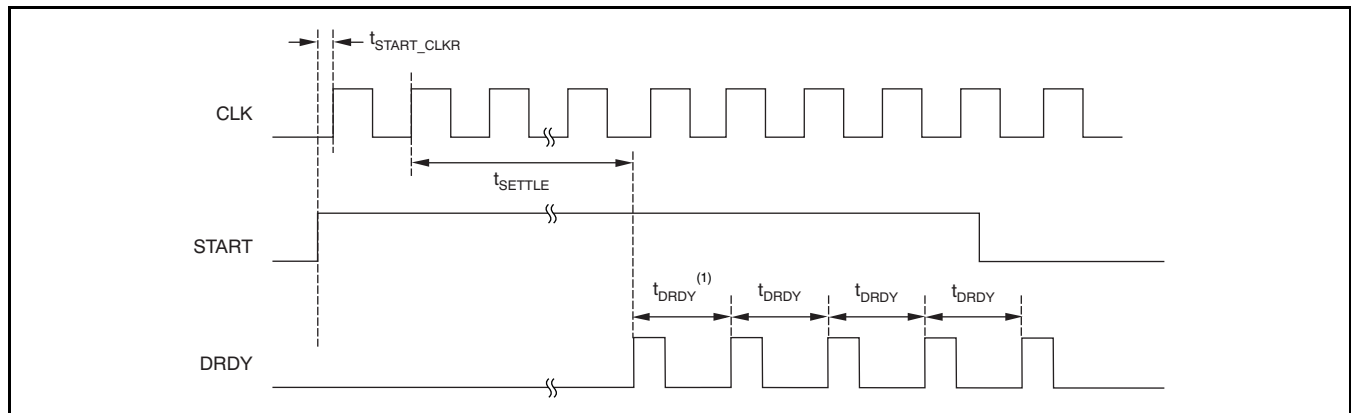

Figure 47. Step Response for Wide-Bandwidth Filter

(1) $t_{DRDY} = 1/f_{DATA}$. See Table 7 for the relationship between t_{SETTLE} and t_{DRDY} when using the Wide-Bandwidth filter.

Figure 48. START Pin Used for Multiple Conversions with Wide-Bandwidth Filter Path

OTRA, OTRD FUNCTIONS

The ADS1675 provides two out-of-range pins (OTRD, OTRA) that can be used in feedback loops to set the dynamic range of the input signal.

The OTRA signal is triggered when the analog input to the modulator exceeds the positive or the negative full-scale range, as shown in Figure 49. This signal is triggered synchronous to CLK and returns low when the input becomes within range. The falling edge of OTRA is synchronized with the falling edge of DRDY. OTRA can be used in feedback loops to correct input over range conditions quicker instead of waiting for the digital filter to settle.

The OTRD function is triggered when the output code of the digital filter exceeds the positive or negative full-scale range. OTRD goes high on the rising edge of DRDY. When the digital output code returns within the full-scale range, OTRD returns low on the next rising edge of DRDY. OTRD can also be used when small out-of-range input glitches must be ignored.

OTRA can be used in feedback loops to correct input over-range conditions quickly.

SERIAL INTERFACE

The ADS1675 offers a flexible and easy-to-use, read-only serial interface designed to connect to a wide range of digital processors, including DSPs, microcontrollers, and FPGAs. In the low-speed modes (DRATE = 000 to 011) the ADS1675 serial interface can be configured to support either standard CMOS voltage swings or low-voltage differential swings (LVDS). In addition, when using standard CMOS voltage swings, SCLK can be internally or externally generated.

The high-speed modes (DRATE = 100, 101) are supported in high-speed LVDS interface mode only.

The state of the LVDS pin and the SCLK_SEL are ignored. In these two modes, an on-chip PLL is used to multiply the input clock (CLK) by three, to be used for the serial interface. This high-speed clock enables all 23-bit output data to be shifted out at the high data rate. The DRDY pulse in this case is three serial clocks wide. The on-chip PLL can lock to input clocks ranging from 8MHz to 32MHz. To conserve power, the PLL is enabled only in the high-speed modes. After power up as well as after the CLK signal is issued, if the CLK frequency is changed, and when switching from low-speed mode to high-speed mode, the PLL needs at least $t_{LPLLSTL}$ to lock on and generate a proper LVDS serial shift clock. Switching among the high-speed modes does not require the user to wait for the PLL to lock. While the PLL is locking on, DOUT and SCLK are held low. After the PLL has locked on, the SCLK pin outputs a continuous clock that is three times the frequency of CLK. The device gives out a DRDY pulse (regardless of the status of the START signal) to indicate that the lock is complete. Disregard the data associated with this DRDY pulse. After this DRDY pulse, it is recommended that the user toggle the start signal before starting to capture data.

The ADS1675 is entirely controlled by pins; there are no registers to program. Connect the I/O pins to the appropriate level to set the desired function. Whenever changing the digital I/O pins that control the ADS1675, be sure to issue a START pulse immediately after the change in order to latch the new values.

Figure 49. OTRA Signal Trigger

USING LVDS OUTPUT SWINGS

When the $\overline{\text{LVDS}}$ pin is set to '0', the ADS1675 outputs are LVDS TIA/EIA-644A compliant. The data out, shift clock, and data ready signals are output on the differential pairs of pins $\text{DOUT}/\overline{\text{DOUT}}$, $\text{SCLK}/\overline{\text{SCLK}}$, and $\text{DRDY}/\overline{\text{DRDY}}$, respectively. The voltage on the outputs is centered on 1.2V and swings approximately 350mV differentially. For more information on the LVDS interface, refer to the document [Low-Voltage Differential Signaling \(LVDS\) Design Notes](#) (literature number SLLA014) available for download at www.ti.com.

When using LVDS, SCLK_SEL must be internally generated. The states of $\overline{\text{SCLK_SEL}}$ pin is ignored. Do not leave these pins floating; they must be tied high or low.

USING CMOS OUTPUT SWINGS

When the $\overline{\text{LVDS}}$ pin is set to '1', the ADS1675 outputs are CMOS-compliant and swing from rail to rail. The data out and data ready signals are output on the differential pairs of pins $\text{DOUT}/\overline{\text{DOUT}}$ and $\text{DRDY}/\overline{\text{DRDY}}$, respectively. Note that these are the same pins used to output LVDS signals when the $\overline{\text{LVDS}}$ pin is set to '0'. DOUT and $\overline{\text{DRDY}}$ are complementary outputs provided for convenience. When not in use, these pins should be left floating.

See the [Serial Shift Clock](#) section for a description of the SCLK and $\overline{\text{SCLK}}$ pins.

DATA OUTPUT (DOUT , $\overline{\text{DOUT}}$)

Data are output serially from the ADS1675, MSB first, on the DOUT and $\overline{\text{DOUT}}$ pins. When LVDS signal swings are used, these two pins act as a differential pair to produce the LVDS-compatible differential output signal. When CMOS signal swings are used, the $\overline{\text{DOUT}}$ pin is the complement of DOUT . If $\overline{\text{DOUT}}$ is not used, it should be left floating.

DATA READY (DRDY , $\overline{\text{DRDY}}$)

Data ready for retrieval are indicated on the DRDY and $\overline{\text{DRDY}}$ pins. When LVDS signal swings are used, these two pins act as a differential pair to produce the LVDS-compatible differential output signal. When CMOS signal swings are used, the $\overline{\text{DRDY}}$ pin is the complement of DRDY . If one of the data ready pins is not used when CMOS swings are selected, it should be left floating.

The DRDY pulse is the primary indicator from the ADS1675 that data are available for retrieval. [Table 6](#) and [Table 7](#) only give approximate values for settling time after a START signal. The rising edge of DRDY should be used as an indicator to start the data capture with the serial shift clock.

SERIAL SHIFT CLOCK (SCLK , $\overline{\text{SCLK}}$, SCLK_SEL)

The serial shift clock SCLK is used to shift out the conversion data, MSB first, onto the Data Output pins. Either an internally- or externally-generated shift clock can be selected using the SCLK_SEL pin. If SCLK_SEL is set to '0', a free-running shift clock is generated internally from the master clock and outputs on the SCLK and $\overline{\text{SCLK}}$ pins. The $\overline{\text{LVDS}}$ pin determines if the output voltages are CMOS or LVDS. If SCLK_SEL is set to '1' and $\overline{\text{LVDS}}$ is set to '1', the SCLK pin is configured as an input to accept an externally-generated shift clock. In this case, the $\overline{\text{SCLK}}$ pin enters a high-impedance state. When SCLK_SEL is set to '0', the SCLK and $\overline{\text{SCLK}}$ pins are configured as outputs, and the shift clock is generated internally using the master clock input (CLK).

When LVDS signal swings are used, the shift clock is automatically generated internally regardless of the state of SCLK_SEL . In this case, SCLK_SEL cannot be left floating; it must be tied high or low.

[Table 8](#) summarizes the supported serial clock configurations for the ADS1675.

Table 8. Supported Serial Clock Configurations

DIGITAL OUTPUTS	SHIFT CLOCK (SCLK)
LVDS	Internal
CMOS	Internal ($\text{SCLK_SEL} = '0'$)
	External ($\text{SCLK_SEL} = '1'$)

CHIP SELECT ($\overline{\text{CS}}$)

The chip select input ($\overline{\text{CS}}$) allows multiple devices to share a serial bus. When $\overline{\text{CS}}$ is inactive (high), the serial interface is reset and the data output pins DOUT and $\overline{\text{DOUT}}$ enter a high-impedance state. SCLK is internally generated; the SCLK and $\overline{\text{SCLK}}$ output pins also enter a high-impedance state when $\overline{\text{CS}}$ is inactive. The DRDY and $\overline{\text{DRDY}}$ outputs are always active, regardless of the state of the $\overline{\text{CS}}$ output. $\overline{\text{CS}}$ may be permanently tied low when the outputs do not share a bus.

DATA FORMAT

In the low-speed modes, the ADS1675 outputs 24 bits of data in two's complement format. A positive full-scale input produces an output code of 7FFFFFFh, and the negative full-scale input produces an output code of 800000h. The output clips at these codes for signals that exceed full-scale. Table 9 summarizes the ideal output codes for different input signals. When the input is positive out-of-range, exceeding the positive full-scale value of V_{REF} , the output clips to all 7FFFFFFh. Likewise, when the input is negative out-of-range by going below the negative full-scale value of $-V_{REF}$, the output clips to 800000h.

Table 9. Ideal Output Code vs Input Signal

INPUT SIGNAL $V_{IN} = (A_{INP} - A_{INN})$	IDEAL OUTPUT CODE ⁽¹⁾
$\geq V_{REF}$	7FFFFFFh
$\frac{+V_{REF}}{2^{23} - 1}$	000001h
0	000000h
$\frac{-V_{REF}}{2^{23} - 1}$	FFFFFFh
$\leq -V_{REF} \left(\frac{2^{23}}{2^{23} - 1} \right)$	800000h

1. Excludes effects of noise, INL, offset and gain errors.

In the high-speed modes, ADS1675 has 23 bits of resolution.

CLOCK INPUT (CLK)

The ADS1675 requires an external clock signal to be applied to the CLK input pin. The sampling of the modulator is controlled by this clock signal. As with any high-speed data converter, a high-quality clock is essential for optimum performance. Crystal clock oscillators are the recommended CLK source; other sources, such as frequency synthesizers, are usually inadequate. Make sure to avoid excess ringing on the CLK input; keep the trace as short as possible.

For best performance, the CLK duty cycle should be very close to 50%. The rise and fall times of the clock should be less than 1ns and clock amplitude should be equal to AVDD.

Measuring high-frequency, large amplitude signals requires tight control of clock jitter. The uncertainty during sampling of the input from clock jitter limits the maximum achievable SNR. This effect becomes more pronounced with higher frequency and larger magnitude inputs. Fortunately, the ADS1675 oversampling topology reduces clock jitter sensitivity over that of Nyquist rate converters, such as pipeline and SAR converters, by at least a factor of $\sqrt{8}$.

SYNCHRONIZING MULTIPLE ADS1675s

The START pin should be applied at power-up and resets the ADS1675 filters. START begins the conversion process, and the START pin enables simultaneous sampling with multiple ADS1675s in multichannel systems. All devices to be synchronized must use a common CLK input.

It is recommended that the START pin be aligned to the falling edge of CLK to ensure proper synchronization because the START signal is internally latched by the ADS1675 on the rising edge of CLK.

With the CLK inputs running, pulse START on the falling edge of CLK, as shown in Figure 50. Afterwards, the converters operate synchronously with the \overline{DRDY} outputs updating simultaneously. After synchronization, \overline{DRDY} is held high until the digital filter has fully settled.

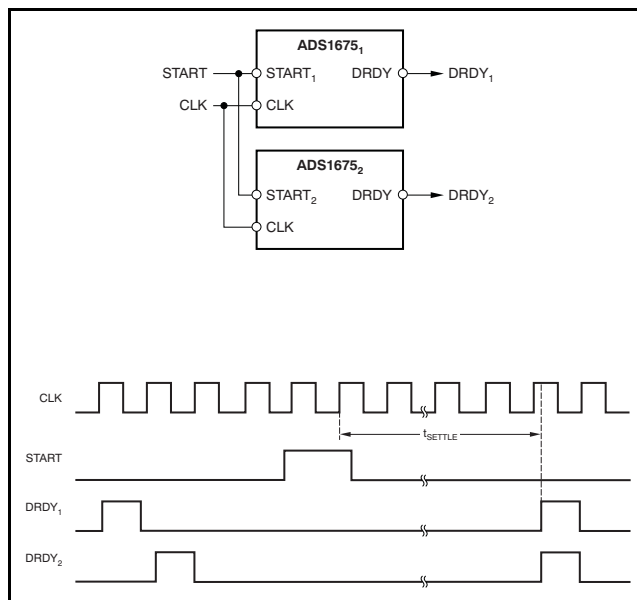

Figure 50. Synchronizing Multiple Converters

ANALOG POWER DISSIPATION

An external resistor connected between the R_{BIAS} pin and the analog ground sets the analog current level, as shown in Figure 51. The current is inversely proportional to the resistor value. Figure 24 to Figure 26 (in the Typical Characteristics) show power and typical performance at values of R_{BIAS} for different CLK frequencies. Notice that the analog current can be reduced when using a slower frequency CLK input because the modulator has more time to settle. Avoid adding any capacitance in parallel to R_{BIAS}, because this additional capacitance interferes with the internal circuitry used to set the biasing.

Figure 51. External Resistor Used to Set Analog Power Dissipation (Depends on f_{CLK})

POWER DOWN (\overline{PDWN})

When not in use, the ADS1675 can be powered down by taking the \overline{PDWN} pin low. All circuitry shuts down,

including the voltage reference. To minimize the digital current during power down, stop the clock signal supplied to the CLK input. Make sure to allow time for the reference to start up after exiting power-down mode.

After the reference has stabilized, allow for the modulator and digital filter to settle before retrieving data.

POWER SUPPLIES

Two supplies are used on the ADS1675: analog (AVDD) and digital (DVDD). Each supply must be suitably bypassed to achieve the best performance. It is recommended that a 1 μ F and 0.1 μ F ceramic capacitor be placed as close to each supply pin as possible. AVDD must be very clean and stable in order to achieve optimum performance from the device.

Connect each supply-pin bypass capacitor to the associated ground. Each main supply bus should also be bypassed with a bank of capacitors from 47 μ F to 0.1 μ F. Figure 52 illustrates the recommended method for ADS1675 power-supply decoupling.

Power-supply pins 53 and 54 are used to drive the internal clock supply circuits and, as such, are very noisy. It is highly recommended that the traces from these pins not be shared or run close to any of the adjacent AVDD or AGND pins of the ADS1675. These pins should be well-decoupled, using a 0.1 μ F ceramic capacitor close to the pins, and immediately terminated into power and ground planes.

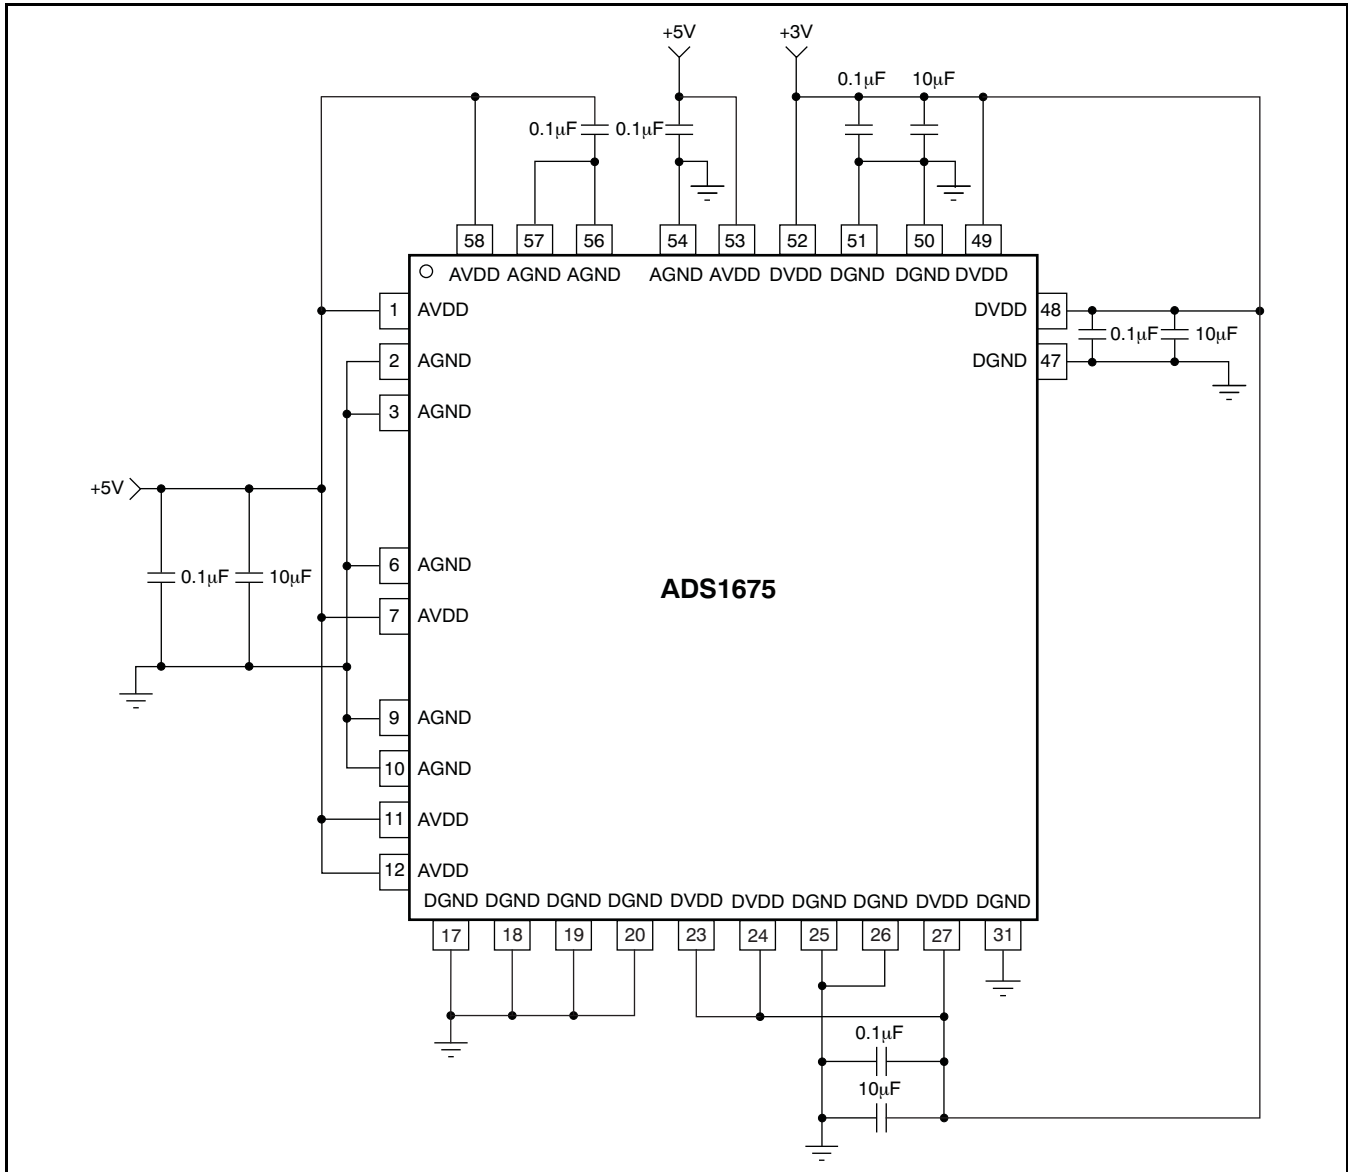

Figure 52. Power-Supply Decoupling

APPLICATION INFORMATION

To obtain the specified performance from the ADS1675, the following layout and component guidelines should be considered.

- 1. Power Supplies:** The device requires two power supplies for operation: DVDD and AVDD. A very clean and stable AVDD supply is needed to achieve optimal performance from the device. For both supplies, use a 10 μ F tantalum capacitor, bypassed with a 0.1 μ F ceramic capacitor, placed close to the device pins. Alternatively, a single 10 μ F ceramic capacitor can be used. The supplies should be relatively free of noise and should not be shared with devices that produce voltage spikes (such as relays, LED display drivers, etc.). If a switching power-supply source is used, the voltage ripple should be low (less than 2mV). The power supplies may be sequenced in any order.
- 2. Ground Plane:** A single ground plane connecting both AGND and DGND pins can be used. If separate digital and analog grounds are used, connect the grounds together at the converter.
- 3. Digital Inputs:** Source terminate the digital inputs to the device with 50 Ω series resistors. The resistors should be placed close to the driving end of the digital source (oscillator, logic gates, DSP, etc.). These resistors help reduce ringing on the digital lines, which may lead to degraded ADC performance.
- 4. Analog/Digital Circuits:** Place analog circuitry (input buffer, reference) and associated tracks together, keeping them away from digital circuitry (DSP, microcontroller, logic). Avoid crossing digital tracks across analog tracks to reduce noise coupling and crosstalk.
- 5. Reference Inputs:** Use a minimum 10 μ F tantalum with a 0.1 μ F ceramic capacitor directly across the reference inputs, VREFP and VREFN. The reference input should be driven by a low-impedance source. For best performance, the reference should have less than 3 μ V_{RMS} broadband noise. For references with higher noise, external reference filtering may be necessary.
- 6. Analog Inputs:** The analog input pins must be driven differentially to achieve specified performance. A true differential driver or transformer (ac applications) can be used for this purpose. Route the analog inputs tracks (AINP, AINN) as a pair from the buffer to the converter using short, direct tracks and away from digital tracks. A 750pF capacitor should be used directly across the analog input pins, AINP and AINN. A low-k dielectric (such as COG or film type) should be used to maintain low THD. Capacitors from each analog input to ground should be used. They should be no larger than 1/10 the size of the difference capacitor (typically 100pF) to preserve the ac common-mode performance.
- 7. Component Placement:** Place the power supply, analog input, and reference input bypass capacitors as close as possible to the device pins. This placement is particularly important for the small-value ceramic capacitors. Surface-mount components are recommended to avoid the higher inductance of leaded components.

Figure 53 through Figure 55 illustrate the basic connections and interfaces that can be used with the ADS1675.

PACKAGING INFORMATION

Orderable Device	Status ⁽¹⁾	Package Type	Package Drawing	Pins	Package Qty	Eco Plan ⁽²⁾	Lead/Ball Finish	MSL Peak Temp ⁽³⁾
ADS1675IPAG	ACTIVE	TQFP	PAG	64	160	Green (RoHS & no Sb/Br)	Cu NiPdAu	Level-4-260C-72 HR

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

PLASTIC QUAD FLATPACK

- NOTES: A. All linear dimensions are in millimeters.
 B. This drawing is subject to change without notice.
 C. Falls within JEDEC MS-026

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
